SEVENTEENTH ANNUAL REPORT

OF THE

PROVINCIAL BOARD OF HEALTH.

INTRODUCTION.

To His Honour the Honourable SIR OLIVER MOWAT, K. G. M. G., Lieutenant-Governor of Ontario.

MAY IT PLEASE YOUR HONOUR:

The Provincial Board of Health, in presenting this its seventeenth annual report, has pleasure in again adverting to the conditions of the public health throughout the past year, as having been favorable, no epidemic has to any extent prevailed, so as to cause general suffering, although complaints have reached the Board that certain lighter infectious troubles were found to exist among the children on the assembling of the schools after the autumn vacations. The Board took steps to inquire into these. The duties of the Board have through the year consisted very much in seeing to the water supply of various localities, and investigating complaints regarding the pollution of streams. The complainants were on one occasion the farmers living on the banks of a small river which before reaching their farms received the sewage of a town of some consideration. It was found difficult to effect a *modus vivendi* between the disputants, and the dairy interests of the neighbourhood possibly still suffer, more than need be, from the mingling in their streams of the impurities of the town. The Board has to regret that in this as in other instances it has found interests which were only seemingly conflicting very difficult to reconcile. Although no epidemic has prevailed, yet one disease of that nature, "smallpox," has appeared in several quarters, introduced first from without the Province, showing its usual disposition to spread in whatever quarter it appeared. The active interference of the Secretary of the Board, who visited many of the localities where the disease was reported to be, causing due measures to be taken for the isolation of infected persons, prevented the prevalence of the disease from including much territory. In connection with smallpox, it seems right to report there is at present a greater risk of its attaining prevalence wherever it gets introduced by reason of an increasing neglect of, and on the part of not a few, even a strong objection to, vaccination. It is to be hoped that public opinion will not permit itself to be further led astray by the fanciful views of certain theorists on this subject, who hold that it is wrong "to provide against the breaking out of one disease by the

infliction of another." There are not wanting, among those who have not attained an old age among us, some who in their European homes have seen the great numbers of scarred and disfigured faces, and the many blind, who have lived and suffered from smallpox before Jenner's great discovery of the results of vaccination became known.

The Board in carrying out its work has still to note as prevailing a comparative indifference with regard to sanitation. That is to say there is not the same appreciation of the value of health laws that is everywhere displayed towards those which care for wealth, and it may be some time before as perfect an organization shall exist because of the one, as exists for the other; but the "Board" looks forward with hope to the time when the value of life and health shall be as highly appreciated as is that of property, and when as competent and as well remunerated officials shall superintend the conditions which appertain to them.

In this introduction to Your Honour of the Report of the Board for the past year, it is not out of place to make especial reference to consumption. More is known of this disease than in former times, but its prevalence continues. It cuts off a greater number of lives than all other infectious diseases combined. The Board has been doing what lies in its power to lessen the incidence of its infection by placing it in the list of notifiable diseases; but if there be any course with regard to it which may in some instances be a practicable preventive, it would seem to be the establishment in fitting localities of hospitals or "homes" whither such as give indications of being affected may betake themselves at a period of the disease early enough for themselves to benefit, as well as for their friends and neighbours to be safe from infection by them.

Respectfully submitted,

J. D. MACDONALD,
Chairman.

ANNUAL REPORT

OF THE

PROVINCIAL BOARD OF HEALTH

OF ONTARIO.

PART I.

CHAPTER I.

REPORT OF THE SECRETARY.

With December of 1898 there ended the first complete year in which, under the Consolidated Act relating to Births, Marriages and Deaths, passed in 1896, monthly reports of all deaths from contagious diseases are returned to the Registrar-General by the 777 Division Registrars of Ontario, and through which returns the Provincial Board of Health is enabled to accurately and promptly estimate the prevalence throughout the Province of those contagious diseases notifiable under the Public Health Act, since the Secretary of the Board is likewise Deputy Registrar-General.

The monthly reports published during the year 1898 represented returns from an average population of 1,840,000 and of 626 registration divisions ; or 80 per cent. of the population was reported upon, and 84 per cent. of the municipal registration divisions.

The following table shows the total deaths from the several diseases reported upon in 1898, as compared with those for the whole Province for the year 1897, taken from the Registrar-General's report of that year :

Table showing the Deaths in Ontario in 1897 and for the Population reported upon by Monthly Returns in 1898.

Year.	Disease.							Totals.
	Smallpox.	Scarlatina.	Diphtheria.	Measles.	Whooping-cough.	Typhoid.	Tuberculosis.	
1897....	169	976	80	163	355	3,154	4,897
1898....	174	387	84	102	579	1,791	2,835

* The monthly returns for 1898 include only deaths from pulmonary tuberculosis or consumption and not other tubercular diseases as of infants and children.

The returns must be looked upon, so far as the more acute contagious diseases are concerned, as representing a high standard of health, both relatively and absolutely, and the Provincial Board of Health as well as the Province has just cause for pleasure that these results are closely associated with its efforts for the improvement of the public health.

Smallpox. The year has been marked, like the two preceding it, by an absence of deaths from this cause; which absence is all the more remarkable in view of the widespread existence of outbreaks of the disease in various states of the American continent. The later months of the year have, however, seen the introduction of the disease into several municipalities which have been succeeded by outbreaks in others in the opening months of 1899. The following table gives the several outbreaks to the end of February, 1899:

Table showing Smallpox Cases in Ontario in 1898 and 1899 to end of February.

County.	Municipality.	Date of outbreak.	Source.	Cases.				Remarks.			
				Total.	Still sick.	Died.	Recovered.	Houses infected.	Houses at present infected.	Isolated in hospital.	Isolated in private houses.
Kent	Camden Tp	Oct. 15	Detroit	4			4	1			4

Essex	N. Colchester Tp	Jan. 1	Detroit	1			1	1			1
"	Windsor City	Mar. 1	"	1	1			1		1	

These repeated appearances of this disease in the Province, it being present in four counties at the time of writing this report, would seem to call for some remarks regarding a disease which in recent years has been the cause of so slight anxiety to the people of Ontario. That it has proved during the past few weeks to still possess all those fatal qualities which have marked its course during the thousands of years since Hindoo Brahmins practised inoculation against its ravages, is seen in the mortality caused by it in three of the outbreaks referred to; and that its contagiousness continues to be of the same intense character has been fully illustrated in the history of the Prescott and Stormont cases.]

Comparative prevalence of smallpox in Ontario. Such being the case, it will be of interest to illustrate, by comparative tables showing the notable decrease in deaths from the disease during the past twenty years, the influence of those methods which have been adopted for suppressing outbreaks of contagious disease. The following table shows the deaths from it in Ontario since the first annual report of the Registrar-General was published in 1869. Remembering that the early reports were defective, and that since the organization of the Provincial Board of Health in 1882, accurate information of every outbreak of smallpox has existed, it may be presumed that a notably larger number of deaths actually occurred prior to that period than is represented by the figures.

Table showing deaths from smallpox, 1869-1898, in ten year periods.

Year.	Deaths.	Year.	Deaths.	Year.	Deaths.
1869	4	1879	195	1889	13
1870	2	1880	143	1890	none
1871	38	1881	5	1891	none
1872	187	1882	15	1892	none
1873	72	1883	4	1893	none
1874	112	1884	63	1894	5
1875	not reported	1885	30	1895	none
1876	31	1886	19	1896	none
1877	45	1887	none	1897	none
1878	36	1888	3	1898	none
Total	527	Total	477	Total	18

The above figures and those in the diagram on a succeeding page illustrate graphically the percentage prevalence of this disease, from which may be gained some idea both of the lives saved to the state and the saving to municipalities in combatting the spread of the disease.

The incidence of the disease, as shown in the tables, was most marked in three series or groups of years, the first, that of 1871-74, being coincident with or following an epidemic prevalence of the disease in Great Britain. The years 1879 and 1880 were also marked by a serious mortality from the disease, as also the years 1884 and 1885. These two latter outbreaks are of much interest, showing by comparison how different were the results as regards general diffusion over the Province of the disease in the two periods, the one preceding and the other following the establishment of a provincial department of health.

That the disease reappears from time to time may be gathered from the following table showing the number of cases introduced into the Province during 1889-98.

Number of Smallpox Outbreaks, Cases and Deaths, 1889-1898.

Year.	No. of outbreaks.	No. of cases.	No. of deaths.	No. of counties affected.	Remarks.
1889.....	2	47	13	2	One outbreak not early diagnosed; cause, infected clothing from Buffalo.
1890.....					
1891.....					
1892.....	1	2	1	1	In person of immigrants. Cases from Chicago and Detroit.
1893.....	2	9	3	3	
1894.....	15	36	5	5	
1895.....					
1896.....					
1897.....					
1898.....	3	13		2	From Detroit.

Of these outbreaks the three serious ones, that of 1889 in Elgin, was due to first cases being diagnosed as measles, and there being no isolation or vaccination till a general exposure and deaths had occurred, it appeared in thirteen houses. The only serious outbreak in 1894, there being fifteen distinct introductions during the year, was similarly due to a first mild unrecognized case, where protective vaccination of exposed persons was not performed.

The Elgin outbreak of 1895 was similarly due to a person, protected by vaccination, having had his clothing exposed in a ward in an hospital where a smallpox patient had been for a few hours. The remarkable fact is illustrated by the outbreaks of 1894, wherein fifteen distinct introductions of the disease occurred, that owing to early diagnosis, vaccination of exposed persons and isolation of houses, but thirty-six cases in all occurred, of the practical protection afforded by vaccination; whereas the twelve deaths in the Elgin outbreak of 1889 not only illustrate the intense contagiousness of the disease of smallpox since the first cases arose from persons at a country dance placing their wraps in a bedroom where two children sick, presumably with chickenpox, were recovering, but also the protective character of vaccination, since not a single one of the persons who died had been vaccinated.

In the succeeding chapter some of the scientific results which modern biological research have given us illustrating the reasons why vaccination has been so rich in its prophylactic effects will be dealt with; as in this has been shown the efficiency of a public health service in dealing with the disease. The resumé therein given will also serve to recall the services to humanity of a discovery which, made a hundred years ago, has in all civilized countries caused what was once the scourge of northern peoples to practically disappear as a cause of mortality. While outbreaks have not failed to make their appearance, the following diagram will make even plainer than tables the truth of the statement as regards Ontario.

Deaths from Smallpox in Ontario - 1869-1898.

CHAPTER II.

THE SCIENTIFIC BASIS OF THE PRACTICE OF VACCINATION AGAINST SMALLPOX.

Everyday experience of life teaches us that the memory of man is essentially short, and history is our teacher that in the political, social or moral sphere man is constantly repeating the mistakes of past centuries and as constantly devising some supposedly new scheme, in essence but a *fac simile* of some old idea, as a panacea for the evils which afflict mankind. To-day we have almost forgotten that smallpox was *par excellence* the scourge of past ages. Macaulay writing of the death of Queen Mary, wife of William III., says: "That disease over which science has achieved a succession of glorious and beneficial victories, was then the most terrible of all the ministers of death. Smallpox was always present, filling up the churchyards with corpses, tormenting with constant fears all whom it had not yet stricken, leaving on those whose lives it spared the hideous traces of its power."

Dr. S. Monkton Copeman in his interesting lectures, referring to a recorded outbreak of smallpox in 1722 in Ware, England, states that the population of the town was given as 2,515 of whom 1,601 are said to have had smallpox previously, the remaining 914 therefore being presumably susceptible to the disease. During the course of the epidemic, of those 914 persons 612 were attacked of whom 72 died." The antiquity of the disease is recognized since history informs us of the practice of how by taking smallpox crusts and by introducing them into the nostrils, the ancient Chinese and Hindoos produced inoculation against the disease.

Later this practice was introduced into England through the writings of Lady Mary Wortley Montagu. Writing from Turkey where she lived as wife of the Ambassador to the Court of the Sultan, she says: "The smallpox, so fatal and so general amongst us, is here entirely harmless by the invention of engrafting, which is the term they give it." So successful did the practice become in England that we are told 20,000 persons were safely inoculated by the two brothers Sutton, carrying out the method of procedure of the famous Sydenham, and without a single death. In practice, however, owing to the lack of any compulsory isolation of such patients the disadvantage resulted that inoculated persons became the vehicle of transmitting the smallpox to others who had not been protected against the disease, so that the total mortality from the disease was rather increased than diminished, the practice not having become general.

Such was the general situation when Dr. Edward Jenner, a student of the famous Dr. John Hunter, and a true scientific investigator, continued his lengthy observations on the protection against smallpox conferred upon the dairy-maids by their contracting cow-pox, a disease prevailing amongst the milch cows of the Gloucestershire district. On May 14th, 1796, it may be said he made the *experimentum crucis* when he inoculated the boy, James Phipps, by inserting lymph from a vesicle on the hand of Sarah Nelmes, a dairy maid, into two superficial incisions in the boy's arm.

It was yet left to Jenner to prove that the boy was proof against smallpox. Dr. Jenner in the following July inserted virus from a smallpox pustule by several similar incisions into the boy's arms. No disease followed. In 1798 Jenner published his investigations, which met with such marvellous public favor that within a few years the method had become known in every part of the civilized world.

So much for the fact of prophylaxis against smallpox having been established. The scientific question still remained: Is cow-pox or vaccinia the same disease in the cow as smallpox in man, only modified? Experimentation from 1801 till the present has gone on, and much discussion *pro* and *con* has taken place. Dr. S. M. Copeman in his lectures on the Natural History of Vaccinia tells how Gassner of Ganzburg in 1801, after ten fruitless attempts succeeded in inoculating a cow with smallpox, from which a series of vaccinations of children were made, each child in the two series proving refractory to

smallpox. Theile of Kasan in 1836 similarly succeeded in inoculating the cow with smallpox matter and in vaccinating children again from the cow. Badcock of Brighton carried on similar experiments through a period of 25 years, making 500 variolous experiments, and succeeded in establishing a regular depot for vaccine lymph, supplying it for thousands of children.

Later, however, the Society of Medical Sciences of Lyons began in 1865 a series of experiments, which seem to have proved that whatever lymph was got from any cases of successful bovine inoculation from smallpox patients was the smallpox lymph and caused true smallpox when inoculated into human beings.

In 1881 Voigt of the Hamburg Vaccine Establishment brought into extensive use in Germany vaccine from cows, due to a previous variolous inoculation.

Other similar experiments with similar results in different countries pointing to variations in results still leave as a matter of discussion the question of whether variola and vaccinia are the same disease modified by appearing in different species, or whether they are two distinct diseases.

Referring to the most recent experiments in which all the care due to antiseptic methods has been practiced we find that Dr. Copeman, in a series of experiments in 1892, succeeded in inoculating three calves with smallpox matter in succession, making them immune against vaccination with vaccine lymph, and in one of these obtained distinct vesiculation in several of the incisions. He also showed that by passages through a series of animals the lymph may become greatly modified. To quote Copeman's words: "The final result has, however, after a greater or less number of removes from calf to calf, been invariably the same—namely, a local vesicle is produced which by no means at our command, such as the appearance and course thereof or the protective power of the lymph derived therefrom, is distinguishable from true vaccinia."

On the other hand, Hervieux (1895), the director of the Vaccine Institute attached to the Académie de Médecine, Paris, asserts the only point of similarity between variola and vaccinia is in the likeness between the vesicles. Copeman, however, insists that if variolous matter can by a series of passages through calves be brought to a point where its lymph produces no more serious results than ordinary vaccine lymph, if it is equally protective against subsequent vaccinal inoculations and if its vesicles can in no possible way be differentiated from true vaccine vesicles, it may fairly be asserted that vaccinia, (cowpox) is nothing more than variola modified by transmission through the bovine animal. Perhaps he says "the most reasonable interpretation of such results may be that smallpox and vaccinia are both of them descended from a common stock."

We have hitherto dealt with the history of the relationship experimentally shown to exist between smallpox and cowpox, and shall now, making further use of various sources of information, refer to vaccine matter and its preparation. Calf lymph is somewhat more viscid than humanized lymph, and as observed under the microscope contains epithelial debris, a few cells being always visible. Leucocytes are usually present, notably in the mature vesicle, and a few red blood corpuscles may also be present.

Vaccine lymph, especially untreated lymph, stored in capillary tubes tends to become turbid or cloudy. This opacity, often like a central whitish thread in a clear fluid, culture experiments show to be bacterial colonies usually proportioned to the degree of opacity of the lymph, these colonies being especially of aerobes present in the lymph before storage in the tubes, which have subsequently developed in the lymph. The lymph or plasma of vaccine is at first faintly alkaline, but tends to become distinctly acid on storing after a length of time.

This serum contains, in addition to the vital activity of the specific organism peculiar to vaccine, an antitoxin or toxin—at any rate some product—possibly of the nature of a toxin or ptomaine which results from the vital activity of the specific organism peculiar to vaccinia.

What this organism is has been the study for years by many bacteriologists, and Copeman details in his series of lectures much of the work done and particularly that by

himself with Dr. Blaxall, in which it is stated that they were able to cultivate from the pulp taken from smallpox vesicles, inserted into an egg and kept in the incubator for a month, a very small bacillus by which inoculations made in calves produced vesicles which after passages through several animals produced a modified virus which was successfully used in vaccinating children, producing results in every way comparable to normal vaccinia. Both calves and children so vaccinated remained refractory to further vaccination with ordinary vaccine lymph.

Copeman further investigated the protective effects of both vaccine and variolous matter on monkeys, showing successful results, vesicles being about complete by the eighth day in each, that by variolous matter showing, however, more of a crust than the vaccine, and producing in some cases an eruption over the whole body. The constitutional effects were more severe with variolous matter, causing fever, diarrhoea, suffusion of the eyes and a peculiar odour.

Further experiments proved that whether vaccinated by vaccinal or variolous lymph, these monkeys proved immune to further vaccinations, even when performed months afterwards.

Until very recently, much later than in America, the practice of vaccination in England has been by arm to arm vaccination, but latterly an animal vaccine establishment has been instituted by the Local Government Board. The arguments for the use of animal vaccine are: (1) The general belief that arm to arm vaccination has become through years of transmission from person to person less protective through the nature of the lymph; (2) That other human diseases may be transmitted during the operation, such as erysipelas, syphilis and tuberculosis.

Inasmuch, however, as it has been found difficult to produce such animal vaccine from vesicles free from the presence of the ordinary pus microbes, attempts have been made since 1891, by Copeman and latterly by many others, to prepare lymph free from other germs, and the practice has now become common to prepare it for the double purpose of obviating any injurious results from their presence in inoculations, and, second, to prevent by their multiplication deleterious effects on the vaccine after being stored.

In 1896 a German commission, Dr. Koch with others, investigated the best means of preserving lymph, and in that report they state (1) that fresh lymph contains numerous microbes, whose number decreases on the addition of glycerine. Thus the commission found the streptococcus destroyed in eleven days and diphtheria bacilli in twenty days by this means.

They further found that the mixture of glycerine with distilled water could be employed to the extent of fifteen to twenty times the weight of vesicle pulp collected, without interfering with its value for vaccination purposes. Copeman and Blaxall further found that vaccine could in this way be freed from pathogenic bacteria, as those of tubercle and erysipelas, even when added in considerable quantities. This is when used in the strength of forty to fifty per cent. of glycerine. Mr. Copeman thus summarizes the advantages of glycerinated lymph:

(1) The method increases largely the amount which can be obtained without any deterioration in its quality to produce successful vaccination; (2) Glycerinated lymph does not dry up so quickly, thus simplifying the process of vaccination; (3) It does not coagulate in the capillary tube; (4) Glycerinated lymph can be produced absolutely free from the various streptococci and staphylococci usually found in untreated calf lymph; (5) The streptococcus of erysipelas, should it be present, is rapidly killed in the glycerinated lymph; (6) Tubercle bacillus is killed even if found in quantity; (7) The possibility of syphilis is eliminated; (8) The bacteriological purity and clinical activity of large quantities of lymph can be tested prior to distribution; (9) The readiness with which glycerinated lymph may be kept on hand for considerable periods of time without any practical deterioration makes its usefulness in any emergency, as where smallpox breaks out, apparent; (10) The expense of producing it is small since the amount obtainable from each calf is enormously increased.

The practice in the preparation of the lymph is after removal of the pulp from the vesicles to mix this with six times its weight of fifty per cent. solution of pure glycerine in distilled water, and thereafter store it in a cool, dark place week by week. Agar-agar cultures are made from it, each week showing a diminution of the microbes present until at the end of the fourth week the culture plates show no further development of colonies of microbes.

The duration of the activity of the lymph varies with the animal vaccinated, and upon the fineness of division of the pulp. Lymph stored for 32 weeks gave in 61 children vaccinated in five places a mean incision success of 98 per cent.

Of course, as Copeman remarks, all the stages in its preparation must be conducted with much care in order to procure these results. One of the chief requisites is that stable and laboratory be of such a character as to reduce the danger of extraneous organisms to a minimum.

Scientific methods having become developed to that point where vaccine matter is now obtainable in pure cultures, with an absolute certainty of successful vaccinations free from any mixed infection or inoculation with pathogenic germs, we are in a position to demand of the public not only the recognition of that protection against smallpox from vaccination which as already seen has resulted since Jenner's discovery over a hundred years ago, but also a ready acquiescence in having a practice carried out in their families absolutely free from any of the possible dangers which its opponents have hitherto asserted have existed.

It is quite remarkable, however, how the outbreak of a case of smallpox in the Province, and the proclamation of compulsory vaccination, at least in the municipality where the case has occurred, calls forth the newspaper correspondent, who always quotes from pamphlets statements, which, perhaps excusable fifteen years ago, shew, in their very use of obsolete terms, antedating even the birth-day of bacteriological science, an absolute ignorance of the advances in the work already summarized regarding the preparation of aseptic vaccine, and of the relations which vaccination with it has, as regards its immunizing properties against disease, to the long series of perfectly demonstrated facts regarding the anti-toxine of diphtheria and the several other diseases in which serum therapy is looked upon as one of the most marvellous outcomes of modern biological science. Writing this report with a view to educating the public, as well as to strengthen the faith of any doubters even in the medical profession, there is introduced here a diagram so neatly setting forth the facts of the protective effects of vaccination, as referred to in the first chapter, that it is reproduced from Stevensson and Murphy's Treatise on Hygiene, taken from the Report by Dr. Barry, of the Local Government Board, England, on the Sheffield smallpox hospitals.

NOTE. Cases with regard to which the Hospital records were incomplete have not been included in this diagram.

From Report on Smallpox in Sheffield, England, by Dr. Barry, Local Government Board

As is remarked by the author of the extremely valuable article on smallpox and vaccination in that text book, the value of vaccination is to be learned, not only from the general absence of smallpox but from its occasional presence.

While such statistics as those set forth in the diagram are but the repetition of results everywhere, it cannot be overlooked that in view of the compulsory nature of the legislation regarding vaccination in Canada, as in most other civilized countries, the responsibility resting upon governments and all public authorities of supplying conditions under which the most absolute protection must be given to those to in whom the operation requires to be performed is beyond question. In a prolonged and very interesting discussion in 1897, introduced before the Medico-Legal Society of New York, by Dr. M. R. Levenson, the following was supplied by your secretary, as his summary of the present position of vaccination, the reasonableness of which the further work on serum immunity during the last ten years has seemed only to strengthen.

“Referring to the question in a five minutes’ discussion, it may be broadly stated that compulsory vaccination has, in my opinion, passed both its medical and legal phases, and is simply one of many questions in “social evolution.”

To orient the problem :

1st. The statistics of a century have absolutely demonstrated that by compulsory vaccination, smallpox has been, and can be eliminated from the category of diseases.

2nd. That even with a compulsory vaccination law imperfectly administered, varioloid is a disease less fatal than measles.

3rd. That the objections which have been taken to the practice of inoculating healthy persons with the materies morbi of attenuated smallpox, cannot be from the standpoint of a lack in its prophylactic efficiency ; but from (*a*) the dangers which may accrue to a patient of inflammatory complications during the progress of the vaccinia, and (*b*) of dangers due to impure vaccine lymph.

4th. Were there to-day practical objections owing to deaths resulting from either cause through the operation, it must at once be admitted that compulsory vaccination is vicious legislation, as contributing directly to the injury of the individual and therefore to the state and not to be defended.

5th. In practice, such objections do not exist, since with the preparation of lymph, under the direct supervision of trained bacteriologists, its action may be obtained in a normal manner without any lessening of its potency, while the absence of dangerous mixed infections in the lymph may be wholly prevented. The surgical operation is of all the simplest, and infection, through the operation, is to be set down to defective surgery.

6th. While, however, compulsory vaccination has, in my opinion, more than justified itself, the practical question of how the law should be applied is pertinent to the discussion. Were vaccination universal and systematic in practice, it would soon not be necessary, as the disease would be eradicated. Inasmuch, however, as immigrant and other travel keeps introducing the disease into seaports and other large cities with dense populations, the compulsory vaccination of school children as a routine measure is demanded.

7th. In Canada this has not been found continuously necessary in rural districts, though still carried out in many sections, owing to the fact that sanitary organization has attained a degree of development by which a centre of infection is promptly isolated ; persons within the radius of the infection are compulsorily vaccinated, and should accident have seemed likely to have caused many to be exposed, whole districts may under proclamation of the state or municipal authorities be at once brought under the operation of the compulsory Act.

8th. In conclusion, it may be stated that while in practice, with smallpox present or in the vicinity of any district, vaccination is carried out generally under compulsory law with penalties attached, yet it seems reasonable that inasmuch as the refusal in individual cases to have the operation performed, which may be due to personal fears of inoculation and is lacking in those qualities which would create a moral wrong, such refusal can be met successfully by compulsory quarantine of persons or families at their own expense during periods of immediate danger, and of enforcing non-attendance of unvaccinated children at school ; since the parents of such children have no right to claim educational advantages from the State which holds that compulsory vaccination of all school children, as in a large city, is necessary to the welfare of the State and the safety of its citizens.

* H.

But it is further of special interest and importance to illustrate how scientific methods are still further elucidating the fundamentally scientific basis of the practice of vaccination by showing that as in diphtheria, anthrax, bubonic plague, rinderpest, typhoid and other diseases, the presence of the disease germs or their toxins in the system of men and animals there produces what are called anti-toxins, which in some manner create a vital resistance of the system for longer or shorter periods to the disease, which has been introduced. Of this class of work relating to the immunizing effects of vaccination through the production in the blood serum of an anti-toxin to both vaccinia and variola or smallpox, I shall give the summary of some remarkable experiments carried on in Paris, France.*

The experiments and reports thereon are by M. M. A. Bécclère et Chambon et Menard, directors of the Institute of Animal Vaccine, Paris.

The experimental study shows that the serum of a vaccinated heifer has some immunizing properties against inoculated vaccine. Such serum injected into an animal of the same species just before a number of subepidermic inoculations causes to some extent incomplete immunization, but yet sufficient to render sterile a large number of the inoculations made, to give the others a rudimentary and aborted appearance and especially causing such to lose all appreciable virulence of the lymph, since it will not inoculate either infants or heifers. The modifying of the virulence of the lymph is much more marked than the change in the appearance of the vesicle. This modification reveals itself even when the inoculation with lymph is delayed one or two days. Thus the serum exerts not only a preventive power but a curative power. Though still much more feeble than the curative power following later after inoculation from a vesicle, this immunizing action always shows itself very rapidly. The immunity conferred by vaccine virus on the other hand develops but slowly; indeed not till after eight days. It is only after the lapse of such a period that similar inoculations made remain sterile.

In the first experiments a definite amount of vaccine was injected under the skin, which was followed by a series of inoculations made on the skin in the usual way, with the interval of a day between, in the first heifer; ~~then~~ after two days, in the second; after three days in the third, and so on.

The following summarized give the results of the several experiments when the inoculation with vaccine was delayed three days: *Experiment 1*: A heifer received an injection under the skin of the left flank with the contents of a large tube of vaccine, formed of glycerinated pulp prepared ten months previously (the amount being about five centigrammes of boiled water, five centigrammes of glycerine and ten centigrammes of the pulp scraped from the vesicles.)

Three days after, the animal was inoculated with vaccine virus on both sides of the body, by linear incisions of two centimetres in length, three or four centimetres apart, to the number of 80 to 120 on each side.

At the same time a test animal injected was vaccinated in the same manner. In both the vaccinal eruption appeared after the usual interval, with normal appearances, practically the same in both. All the inoculations gave rise to vesicles. From both, two collections of vaccine lymph, twenty-four hours apart were taken. From both, also, a glycerinated pulp was prepared dating from the 4th, 5th and 6th day from the date of inoculation. Those from the test animal were considered as normal and used for comparison as to virulence of that from the injected animal.

To this end with proper precautions non-vaccinated infants were vaccinated with three punctures on each arm, on the right arm with one of the three normal vaccines and at the same time on the left arm with lymph of same date from the experimental animal. Five infants were vaccinated on the right arm with normal vaccine and, on the left with test lymph taken on fourth day; eight infants with lymph taken on fifth day and seven infants with lymph taken on sixth day. On all the infants the inoculations gave beautiful

*See Annales de l'Institut Pasteur, Nos. for Dec., 1898, Jan. and Feb., 1899.

vaccine vesicles, without notable differences on the two arms. There exists, therefore, no appreciable difference in the vesicles from the two sources and of corresponding age.

Experiment 2.—Where a heifer was injected with a glycerinated lymph of two and a half months standing; after four days this animal was inoculated with the same lymph in the manner already described. At the same time a test animal was vaccinated. The evolution of the vaccine vesicle in the two was very different. Three days after the inoculation the test animal not only does not show any swelling about the incisions, not even any thickening of the skin, and no redness; it still is in the incubation stage. At the same time the experimental animal shows an eruption manifestly premature, more advanced, even in its evolution, than another animal vaccinated twenty-four hours earlier. All its incisions are surrounded with a very marked red areola, indicating a strong congestion, the subjacent tissue is infiltrated to the point of forming a notable elevation to sight and touch. Six days after the injections beneath the skin, the eruption of the experimental animal is composed of large pustules, prominent, wide, filled with an opaque liquid, and surrounded with a zone of great congestion, several inoculations, however, being partly aborted.

These pustules are for the most part remarkable from their festooned contours and polycyclic, a certain indication that the inoculated germs have not developed fully and that each pustule is formed by the re-union of only a small number of sub-epidermic colonies, only, however, three or four. On the test animal the eruptive elements are much less large, less prominent, filled with a fluid still mostly transparent. Some, however, are opaque, without a congested tint at the periphery. They have regular contours, evenly outlined, and not appearing formed, as those in the experimental animal by the confluence of three or four vesicles first rounded.

From the experimental animal, at intervals of twenty-four hours, lymph is taken in three lots, and a glycerinated pulp is prepared in three lots, dating the fourth, fifth and sixth days after the sub-epidermic inoculations.

To measure the virulence of each of the three vaccines non-vaccinated infants were inoculated as before on each arm, the right with normal vaccine taken from the test animal six days after inoculation, the left with lymph from the test animal taken on the fourth day after inoculation; also infants with fifth and sixth day experimental lymph. On all the infants the vesicles on both arms show no differences. There seems, then, no difference in virulence in the two lymphs. It is notable, however, that the fourth day lymph gives vesicles particularly large and prominent, more beautiful than those coming on the same subjects from normal vaccine. It has, then, an accentuated virulence.

Experiment 3.—Made after a sub-cutaneous injection five days preceding the inoculation gave as results:

- (a) Matured vesicles twenty-four hours at least before the non-injected test animal.
- (b) Vesicles notably modified in external appearance and arrested in its development.
- (c) A lymph of normal virulence five days after inoculations, of very attenuated virulence after six days.

Experiment 4.—Made after an injection preceding by six days the inoculation giving as a result:

- (a) Vesicles developed about twenty-four hours sooner than the normal.
- (b) Vesicles very much modified in external aspect, rapidly and notably arrested in their development.
- (c) Vesicles containing a lymph of almost no virulence four days after inoculation, and of no virulence five days after inoculation.

Experiment 5.—The injection preceding the inoculation by seven days gave as results:

- (a) Vesicles appearing about twenty-four hours in advance of normal vaccination.

(b) Vesicles very modified in external appearance, rapidly arrested or aborted in their development.

(c) Lymph with almost no virulence four days after inoculation, and no virulence five days after inoculation.

These various experiments confirm the fact that the immunity following sub-cutaneous injection in its period of gradual development from the fourth to the eighth day shows itself externally by an arrest of development, more or less pronounced, of the eruptive elements. The proportion of sterile inoculations, or almost sterile, increases with the daily progress of the immunity and enables us to measure with the eye its increasing degree.

The experiments further show that with the arrest of the eruptive elements there corresponds an attenuation more or less complete of their contained lymph. With these signs are revealed and measured the gradually increasing immunity as the days follow the sub-cutaneous inoculation of vaccine virus.

In these two ways, also, has been revealed and measured the immunizing action, both preventive and curative, of the serum of a vaccinated heifer; this is not a single action *but comports in a series of varying degrees with the doses of serum injected and with the time of injection.*

The principal fact developed by these new researches is that in heifers successively injected under the skin and inoculated upon the epidermis, there results between the subcutaneous vaccination and the complete loss of virulence of vaccine lymph an interval of at least eleven or twelve days.

The same experiments performed on guinea pigs gave similar results.

The protective action of serum as shown by its effects upon the vaccine virus has been studied with the serum of convalescents from smallpox, from vaccinated horses, vaccinated men, and from animals inoculated with smallpox virus. All have been found to comport themselves similarly as opposed to activity of vaccine virus.

M. André Jousset, has studied the physical and chemical qualities of the special substance which gives this property to such serums.

It has been clearly proved that the serum from such vaccinated animals mixed with fresh vaccine at once renders it inert.

Thus a non-vaccinated heifer is aseptically bled by a puncture in the jugular. It is then vaccinated in the usual manner by multiple incisions. The eruption appears in the usual manner. Fourteen days after the vaccination it is bled a second time. These two bleedings yield two serums taken aseptically. A test-tube is almost completely filled with a sample of each serum of 5 to 6 c.c.

To each is added the contents of two or three tubes of vaccinal pulp of same crop. The tubes are carefully shaken, covered with rubber caps sterilized. They are then laid horizontally to aid complete mixing of serum and pulp. At the end of 24 hours they are shaken again, placed vertically and the pulp allowed to settle. After another 24 hours, by aspiration, almost all of the two test serums and the mixture of serum and vaccine pulp in each tube is placed in sealed tubes. Thus then are two vaccines prepared in the same manner from the two animals. To test their virulence, it is only necessary to vaccinate the same animal on different sides of the body. This was usually practised in the inside of either thigh.

Thus the left side was vaccinated with 15 incisions with vaccine treated with serum from non-vaccinated heifer, and the right side with that from the vaccinated animal. This animal is immediately vaccinated on the side of the belly with fresh vaccine virus which has not been in contact with any serum. After six days the eruption is at its height, the normal vesicles of the flanks show the receptivity of the animal. The vesicles on the perineal spaces may thus after another day has elapsed be accurately compared with the normal vesicles. It is found that the inoculations with lymph mixed with serum from the non-vaccinated heifer have produced perfect vesicles and have lost nothing

of their virulence. On the other hand, the vaccine mixed with serum from the vaccinated heifer has not produced any appreciable result, and practically no inflammatory action. Thus it may be said that the serum of the vaccinated animal produces on the vaccine virus most certainly anti-virulent effects, to say the least; in the same way as we speak of the antitoxic and the anti-venomous effects of certain serums.

Experiment in 36 cases on horses treated in the same manner as the heifer produced identical results.

Similarly, 30 experiments were made on human subjects. Each patient was bled, yielding 20-30 grammes of blood by a hypodermic syringe introduced into a vein of the arm.

The case of a woman 44 years old, vaccinated in infancy, is given. She was bled then three days after was inoculated on left arm by three incisions with fresh vaccine from the heifer, which gave beautiful vesicles, showing no trace of the immunity of infancy. Some 32 days after this vaccination, some blood was again taken from the woman. The serum taken from the patient bled, studied in its action on the vaccine virus, comparatively with that taken from the unvaccinated heifer, resulted as follows:—The left side of the perineum of an unvaccinated heifer is vaccinated with lymph treated with serum of an unvaccinated heifer, while the right side was vaccinated with vaccine treated with the lymph from the woman vaccinated a month before. The result was that the vesicles on the left side were perfect, and those on the right side were aborted as in the previous case of the heifer.

In the next experiments, the effects of mixing vaccine with serum from patients recovering from smallpox, were shown. Blood was taken from ten patients. Thus a man was bled on the 23rd day of the disease, the 20th from the beginning of the eruption. Some days later a heifer was inoculated as before with vaccine bottled for 48 hours, taken as above from the patient. Compared with fresh vaccine not so treated, the incisions showed the complete anti-virulent action of the blood serum. The same results exactly were got by vaccinating a child on both arms; the one with fresh vaccine, and the other arm with vaccine treated with lymph. The one arm had a perfect vaccination, the other produced no reaction whatever.

These experimenters further tested the serum of monkeys, which they succeeded with alone amongst lower animals in inoculating with lymph from vesicles in smallpox patients. On the fourth day after inoculation, the forty-one incisions became papulovesicular, very similar to those of vaccinated children on the fourth day.

The inoculated monkey became sick and died on the 14th day after the inoculation. A few minutes before it died, blood was taken from its femoral artery, giving some 2 c.c. of serum.

A heifer was vaccinated as before on the right side with vaccine treated with this serum; the other side with fresh vaccine. The result was as before, the treated vaccine proved non-virulent.

The lymph from a smallpox vesicle in a woman who had smallpox, and who had been injected with serum from a vaccinated heifer as a therapeutic measure—forty-eight hours before the lymph was taken—proved ineffectual in any attempt to inoculate a monkey with smallpox.

These experimenters have further shown that while they could not inoculate horses and other animals with smallpox by the skin like the monkey, yet by injecting them into the cellular tissue with smallpox lymph, the blood-serum afterwards proved sufficient to make vaccine virus inactive.

Experiments with the serum of vaccinated animals showed that its anti-virulent action was not destroyed by heating to 70° C; and further that its properties were not removed by filtration through a Chamberland filter; and further that the vaccination of the mother shortly before the birth of a child, makes the child immune to vaccine virus.

Summed up, the conclusions of this most interesting series of experiments are :—

1st. The serum of a heifer taken fourteen days after inoculation, is endued not only with immunizing properties, preventive and curative—but it also produces when mixed with vaccine, an anti-virulent effect.

2nd. It produces in horses and probably similar animals, the same anti-virulent properties as in cows and men.

3rd Vaccination produces the anti-virulent property on the serum, however the inoculation be made, whether by the skin, the blood, or the deeper tissues.

4th. The serum from convalescents from smallpox exerts the same anti-virulent action on vaccine as does that from variolized animals, as monkeys.

5th. The anti-virulent substance of the serum of man and animals immunized against vaccine and variola has a stable composition, offers great resistance to heat, light, time, persists when dried and does not readily putrefy.

6th. The blood takes several days after inoculation to acquire anti-virulent properties fully, in the heifer after from nine to thirteen days, and is at the very moment that the vaccine or variolous virus loses all activity.

7th. The period of vaccinal immunity varies much with different species, but the anti-virulent property of the blood goes on decreasing, and may disappear completely, although the skin in the same person may still resist re-inoculation with vaccine.

8th. This anti-virulent property varies with different persons, but persists for twenty-five years and even fifty or over, with persons against variolous and vaccinal infection.

9th. The production of the anti-virulent substance in the course of vaccinal or variolous infection and its appearance in the blood plasma, constitute a reaction of defense of the organism intimately allied to the arrest of the morbid process, and to the development of immunity. We do not yet know whether this substance acts directly on the infective agents as a virulicide or whether it acts as a stimulant on the tissue cells of the organism.

CHAPTER III.

VARIATIONS IN THE VIRULENCE AND INFECTIOUSNESS OF PATHOGENIC MICRO-ORGANISMS.*

When we consider the infectiousness of a micro-organism or the gravity of the manifestations of its virulence in an infected animal, we recognize at once, that there frequently exist wide variations in intensity. These variations may be due to either a difference in the resistance of the infected organism, that is to a variation in immunity, or to a greater or lesser degree of power to infect, that is to a variation in the virulence in the virus.

That natural immunity may vary considerably is well known, and that unfavorable hygienic conditions of all kinds are potent influences in diminishing this natural immunity is also recognized; but in many infectious diseases, epidemiological studies show that the more important factor in determining the morbidity and mortality is the virulence of the virus.

It is true that the two conditions of immunity and virulence act and react on one another, and in many instances may be separated with difficulty. We must admit that an organism of low virulence may infect an animal with slight natural immunity, whilst the same organism would not infect another animal with marked natural immunity; but if we take such a specific instance as the history of diphtheria in England during the present century, we see that, in spite of improved hygienic conditions, the mortality rate, until the introduction of anti-toxin, has varied but little, and whatever variation has occurred has been more cyclic in character, rising gradually through a series of years to a maximum, then falling to again rise.

If we look more closely into the history of diphtheria, we see everywhere evidence of this variation in virulence of the diphtheria bacillus.

The percentage mortality of diphtheria in Europe, without anti-toxin treatment is undoubtedly higher than in America, notably higher than in Ontario. Looking at European statistics as a whole we find a mortality rarely under thirty per cent, and frequently as high as thirty-seven per cent. On the other hand Ontario statistics show a much lower mortality even with our undoubtedly incomplete morbidity returns. But in Ontario itself we find great variations in different cities and towns and in the same town in different years.

If we take, for example, the statistics of such a city as Brantford, in which notification has been fairly thoroughly carried out, we find the following results:

For the years inclusive of 1890 to 1895 there were 384 cases with 49 deaths, or 12.07 percentage.

For the individual years the returns are:

	Percentage.		Percentage.
1890	11.5	1893.	11.1
1891... ..	15.0	1894.....	13.8
1892	4.0	1895.....	21.1

As a rule the percentage mortality in Ontario is under twenty, but occasionally we find that it runs much higher, for instance:

Hamilton.	Per cent.	Ottawa.	Per cent.
1893.....	25.5	1892.....	30.0
1891.....	37.5	1894.....	29.9
		1895.....	27.9
Stratford.	Per cent.	Stratford.	Per cent.
1891.. ..	46.1	1892.....	25.0

*By J. J. Mackenzie, B.A., Bacteriologist to Provincial Board of Health.

The only explanation of these variations is a difference in virulence in the infecting bacillus.

From time to time the diphtheria bacillus has been isolated in pure culture from cases sent in to the laboratory for diagnosis, and I have tested the virulence of the pure cultures for guinea pigs. It is, of course, impossible to draw exact conclusions from the virulence of the bacillus for guinea pigs, as to its virulence for man, as many experiments have shown that this is unsafe; but the facts are interesting as indicating the extent of variation. The results are as follows:

Experiment A.—Specimen isolated from a larynx at an inquest, two weeks after burial:

Dose.	Weight of guinea pig.	Result.
1 c.c. 48 hour bouillon culture	450 grms.	Death in two days.

Experiment B.—Specimen isolated from an infected throat three months after the disappearance of the membrane:

Dose.	Result.
1 c.c. 48 hour bouillon culture	Death in two days.

Experiment C.—From mild case of diphtheria, with very slight exudate:

Dose.	Result.
0.5 c.c. 48 hour bouillon culture	Death in five days.

Experiment D.—From case of otitis media (disease of middle ear):

1 c.c. 48 hour bouillon culture	Induration at point of inoculation; animal recovered.
---------------------------------------	---

Experiment E.—From infected nose (A. M.); no clinical diphtheria; no discharge from nose:

0.99 c.c. 48 hour bouillon culture, weight of guinea pig 500 grms	Animal died on 15th day. Extensive necrosis of skin.
--	--

Experiment F.—From mild diphtheria A. B.:

0.99 c.c. 48 hour bouillon culture, weight of guinea pig 500 grms ..	Animal did not die, lost weight and had extensive area of necrosis of skin.
--	---

Experiment G.—From nasal discharge S. U.:

1.09 c.c. 48 hour bouillon culture, weight of guinea pig 500 grms.....	Animal died in 18 days.
--	-------------------------

Experiment H.—From slight sore throat, U. K.:

0.99 c.c. 48 hour bouillon culture, weight of guinea pig 500 grms.....	Animal died in 18 days.
--	-------------------------

Experiment I.—From infected throat:

0.98 c.c. 48 hour bouillon culture, weight of guinea pig 500 grms..	Animal lost weight and showed extensive infiltration of skin but did not die.
---	---

Experiment K.—From severe laryngeal diphtheria:

1 c.c. 48 hour bouillon culture	Animal died in 48 hours.
---------------------------------------	--------------------------

It will be seen from these results of experiments that for the guinea pig there may be a very marked variation in virulence. All these animals were given approximately the same dose of the culture of bacilli, yet the results were quite different. As a rule we notice also that the most actively virulent cultures came from the most severe infections in man.

When we turn to the bacillus of typhoid we find the same variations in virulence.

In epidemics of typhoid in Ontario we see that the mortality varies considerably in different epidemics and in some instances quite markedly. If we take specific instances, we may refer to two rural epidemics, investigated by the writer which show markedly the effect of virulence. The one occurred in the Township of East Zorra in Oxford County, in October, 1897, the other in the Township of Hamilton, Durham County, in the autumn of 1898. In both cases, it was impossible to trace the origin of the first case but the relationships of subsequent cases were easily traced. In both cases hygienic conditions were apparently the same, the population attacked were of the same class and apparently endowed with the same degree of immunity, that is they belonged to a well-to-do farming class. The East Zorra epidemic showed eighteen cases and eight deaths, the Hamilton epidemic showed twenty cases and one death. As pointed out in the report upon the East Zorra outbreak the most striking characteristic aside from the high

mortality was the evident infectiousness of the virus ; in the Hamilton epidemic, the mortality was low and there was not so much evidence of 'direct contagion, the cases seemingly being traceable rather to polluted water. These facts, then, intense virulence and intense infectiousness seem to go hand in hand and *a priori* one would expect such a connection.

There are many other instances of variation in virulence which might be given but the above will suffice.

An important question from the standpoint of public health is that of the causes of these variations. What are the conditions which determine them ?

Some of these we know from the results of experimental investigation, but all the conditions are not yet thoroughly understood. There seems to be no doubt but that the tendency of pathogenic bacteria is to lose their virulence when allowed to grow outside the body ; that the longer they have grown outside the body the lower their virulence and that once lost it is regained with difficulty. All sorts of conditions produce this. Thus simple cultivation in the laboratory is most effective ; a temperature higher than the optimum for their growth, the presence of substances in the culture medium which tends to weaken the growth. To restore lost virulence on the other hand is a still more difficult problem. The method which is usually adopted in the laboratory is its passage through the animal body. Pasteur found for example that in rabies the virus from dogs, infected with the so-called street virus, varied considerably in virulence. Inoculated into rabbits it produced death in from fifteen to thirty days. When, however, the virus was passed from rabbit to rabbit, the incubation period became shorter, and death followed in a shorter time, until finally a degree of virulence was reached in which the animal invariably died within eight days. This condition remained constant, that is the virulence had reached its acme or it was fixed.

The same observations have been made for the streptococcus. Passage from rabbit to rabbit increases the virulence so that finally a stage is reached where a single cell or microbe is sufficient to produce a fatal septicæmia in the animal.

For typhoid, diphtheria and other diseases, the same fact has been experimentally established. Passage from susceptible animal to susceptible animal will apparently always increase the virulence of a micro-organism.

This fact is a most important one from a public health standpoint ; the rapid spread of an epidemic disease through a susceptible population always results in an increase in virulence of the disease. Many epidemiological observations give support to this view, the most characteristic being the spread of such diseases as measles, smallpox and syphilis amongst aboriginal races. Whenever this has occurred the virus has increased enormously in virulence, not only for the relatively susceptible aborigines but also for the immune white races who may be exposed to the disease. When, therefore, an epidemic disease breaks out in any community the necessity for checking it is two-fold, primarily to lessen the number of cases and secondarily to prevent any possible increase of virulence, due to the rapid passage of the virus from individual to individual.

Aside from the above normal increase in virulence which results from passage through animals we sometimes meet with cases in which there seems to be a sudden increase which is not so easily explained. An example of this is shown by the recent epidemic of smallpox in Ohio. In over a thousand cases the mortality has been less than one per cent. The disease has been so mild as to lead to its being repeatedly overlooked by experienced physicians. The virus from this outbreak, however, has been introduced into Quebec and the French counties of Ontario, with the result that there has been an outbreak of typical smallpox with the usual mortality. Vaccination to a certain extent may account for some of the difference in the virulence of the virus in Ohio and Quebec, but not entirely.

This fact, then, of the gradual or sudden increase in virulence must always be kept in mind when an epidemic occurs, since should it appear, the difficulties of the health officer and physician are correspondingly increased.

Especially do we see the practical utility of thorough isolation of even mild cases of disease, as of scarlatina and diphtheria ; since the contagion spread from child to child, that is from mouth to mouth is as from animal to animal, and therefore possesses a virulence greater than inoculation from infected clothing, or from the air of an infected house. In the latter case many interesting illustrations could be cited of public buildings, such as orphanages, institutions for the blind, and children's hospitals, the air of which, owing doubtless to microbes being present in the dust on floors, walls, etc., seems to be permanently infected. But meanwhile the microbes have become so weakened in virulence in their existence outside the body, as to cease almost to be infective to the inmates, but which will only too readily attack those children who may enter the home, and which have not as it were become immune to infection from that particular atmosphere. This immunity which may be called house acclimatization is on a par with that gradual acclimatization which takes place in the residents of malarial climates, and indicates the aptness of what was stated in the beginning of the chapter, that there are necessarily the two influences acting and re-acting upon each other, viz. : that of virulence and of immunity, both of which are of necessity terms purely relative.

CHAPTER IV.

THE BIOLOGICAL PRINCIPLES INVOLVED IN THE PURIFICATION OF THE SEWAGE OF TOWNS.

While the comparatively small populations of the towns and cities of Ontario, and their location in most cases on the shores of the great lakes and rivers have hitherto made the question of the pollution of streams of relatively little importance, compared with that in the densely populated countries of the world, and of the older industrial States of the American Union, yet the fact that the urban populations of the thirteen cities of Ontario alone amount to 436,000, while but fifty towns and cities are more or less sewered, clearly indicates that the laws against the pollution of streams, contained both in the common law of Canada and the Public Health Act have served and will hereafter still serve to prevent the development of conditions which older countries have found to be the problem most difficult of solution with which urban municipalities have had to deal.

The primary cause in the creation of the problem of sewage disposal has lain in the fact that the waste organic materials from man and animals have been looked upon as having no commercial value commensurate with the cost necessary to their transportation, either as to the land or to their manufacture into any commercial product. Especially has this been true in new countries, such as Ontario, where the virgin fertility of the soil was for many years deemed adequate for yielding, without the cost consequent upon the use of manures and other fertilizers, crops giving a good financial return for the labor involved.

The agricultural experience of the last twenty-five years in the older settled parts of the Province has, however, shown how serious has been the mistake made, and to-day we see that the agriculturists and horticulturists near the larger centres of population are taking every opportunity of using, to their fullest extent, all town refuse, whether manure or oil and waste from various industries, to restore to the soil its lost organic and mineral constituents so necessary to intensive cultivation. The cities of the old world, both of Europe and Asia, have, however, largely added human organic wastes to this class of soil fertilizers, and the Western states of the United States have seen the successful introduction of the Chinese methods in market gardening, wherein nightsoil plays so important a part.

In all this matter, however, we have seen on the part of the agriculturist an absence, first, of an appreciation of the value of and need for such fertilizers, and further, a notable ignorance of their value, and perhaps a still greater dislike to their utilization.

Under such circumstances, it is clear that there has not been cultivated any idea on the part of urban populations of doing anything towards the disposal of town refuse and sewage, except that of adopting the cheapest possible methods for its disposal, compatible with a due regard either for their own safety or the law against pollution of streams. Indeed, we cannot be said to have got beyond this stage since we see our two largest cities, Toronto and Ottawa, discharging all their sewage into Lake Ontario in the one instance, and into the Ottawa river on the other; and it has only been within the past two years that, under legal compulsion, we have seen Hamilton introduce chemical purification sewage works, and London preparing to dispose of her sewage on a sewage farm. The towns of Berlin and Waterloo, situated inland on mere creeks, have been forced to adopt disposal on sewage farms, and it has been only within the past few years that the Government public institutions have instituted methods for dealing with their sewage.

In Ontario, therefore, as in England and elsewhere, the introduction of methods for dealing with town sewage, other than the pollution of water courses, has been and must be, in the nature of things, gradual, being determined in the case of each town by either

a fear of the pollution of its own water supply, or by compulsion through legal action brought by another municipality affected by such pollution, as occurred in 1898 in the case of the city of Stratford.

With a view to encouraging the evolution of sewage disposal works, it therefore seems proper that a chapter should be devoted to the biological principles involved in such.

By "sewage" is meant the liquid contents of a sewer; and, in water-closet towns this means of all human excreta, kitchen slops, washing water and the organic wastes carried to the sewers by storms, from the streets and lanes. In most, indeed in all towns, it means stable drainage, industrial wastes, such often as blood, and even offal from slaughter houses in some cases, and chemicals and refuse from woollen factories, tanneries, gas works, breweries and distilleries and the multiform industries of large towns.

It is, therefore, very apparent that sewage will vary greatly under different circumstance; and indeed, it is this fact which constitutes, as we shall see, one of the chief difficulties in disposing of sewage satisfactorily. Organic wastes, such as wastes from woollen factories and paper mills serve to clog filters rapidly, while gas liquors and other chemicals will at one time tend to destroy the living organisms or microbes which break up organic matters or at another time by their excessive acidity or alkalinity, seriously alter the conditions under which a filter normally performs its work.

In all such instances, however, it is apparent that special measures will have to be adopted for dealing with the sewage at the outfall works at such hours as the discharge from establishments of the kinds indicated arrives there. After all, essentially however, the problem of sewage disposal is one of dealing with the wastes from human habitations, which material may be said to consist of the following constituent parts, along with the mineral matters commonly reaching a sewer.

The analysis of the sewage of an average English town is given as follows:—

1. Solid matters in suspension:

(a) Organic.....	20 grains per gallon.
(b) Mineral ..	10 " "
Total.....	30 " "

2. Solid matters in solution:

(a) Organic....	20 grains per gallon.
(b) Mineral.....	50 " "
Total.....	70 " "

Or expressed in parts per 1,000,000, such a sewage would yield:

Total solids.	Solids in suspension.	Chlorine.	Free ammonia.	Organic ammonia.
1428.0 parts.	428.0 parts.	120.0 parts.	50.0 parts.	10.0 parts.

It will be apparent that the solids in suspension may be quite readily removed in large measure by any crude filtering methods, which may obstruct their onward flow; but that the organic matters in solution must naturally require such treatment as will either obstruct their movement toward the stream toward which the sewage water will ultimately flow, or destroy them by altering them in chemical form will at once be apparent. Besides this there are soluble chemical salts such as the chlorides which are only with difficulty removed from sewage even if it be filtered through soil.

In addition however to the constituents of sewage already given there are microbes or micro-organisms, which are carried into sewage with the excreta of human beings, as either normally or abnormally present in the intestines, as well as various species from the sundry organic constituents of household refuse. In addition to these are, however, the very many other species naturally present in the soil and refuse of streets, lanes, and so on, all of which once carried into the sewers will multiply there, if there be no conditions or substances present inimical to their existence as saprophytes. Besides these there are the various forms present in the air, which always occupies a notable part of the area of sewers.

It is therefore quite manifest that the mineral and dead organic matters in sewage, while forming its major part so far as bulk is concerned, may be, and indeed have in fact proved to be, the least important matter with which we are concerned from the public health standpoint. This is due to the facts, first, that the micro-organisms present in sewage may be in themselves pathogenic or actual producers of disease if taken into the human system either through air or water, and second, that such organisms whether disease germs or not may become saprophytes, growing and multiplying in sewage and there producing organic chemical substances which if taken into the system either through the air or water may prove to be actually toxic to the human or animal system.

The problem then of sewage disposal may be said to be simply: *How shall the organic matters present in sewage be so disposed of with the least cost, as that they shall not create effluxium nuisances either on the surface of the soil, along the banks of streams, or by their excessive presence in the waters of streams; or that they shall not pollute the water of streams which may be drunk either by man or animals with injury to health as the result?*

In order that such a question may be answered intelligently and correctly, it will be necessary to discuss the question of how pathogenic germs are removed from or destroyed in sewage, and of how the organic matters therein are by decomposition reduced to their simpler constituents, as either gases or soluble and insoluble chemical compounds. This process is what has very properly been called by W. D. Scott-Moncrieff, *The biolysis of sewage*, depending as it does principally upon the action of living organisms. He says, "*The problem may resolve itself into the discovery of the methods by which nature can be so aided in the case of sewage that it can be purified on the largest scale at a reasonable cost without creating a nuisance and without the use of chemicals.*"

The biolysis of barnyard manures applied to the ground as fertilizers affords the most familiar example of the destruction of the organic excreta of animals.

The following experiment (in a printed report of the chemist of the Dominion Experimental Farm) illustrates what takes place. He states that equal parts in weight of cow and horse dung were mixed and exposed to the amount of 8,000 pounds, in the open air in April. At the end of the month the manure had been reduced to 5,113 pounds. The organic matter was reduced from 1,938 to 1,093 lbs., or 45 per cent. of the total amount. The total nitrogen present, the total solids being but 30 per cent. of the total weight, was 48 lbs. or about 0.60 per cent. was reduced by 12 lbs. or 25 per cent. during this period. By this decomposition it is stated humus is formed, this being the name applied to semi-decomposed vegetable matter and is that which constitutes the black material in all fertile and productive soils. In a soil rich in humus it is found that micro-organisms are present in immense numbers per gramme of soil, decreasing downwards and that they carry on the decomposition of such organic matters as in virgin soils and manure until ultimately such would become but little more than mere carbon. It is thus seen that the multiplication of such organisms depends upon the presence of abundant organic matter and upon oxygen of the air.

We now know, however, that organic animal matters containing especially nitrogenous matters are capable of being decomposed apart from the presence of the oxygen of the air; in other words such materials may be broken up in water, after the dissolved oxygen has been exhausted by oxidizing processes and appropriated by aerobic organisms.

Mr. Thos. Fuller in his report on Water Purification states regarding the biological principles involved in sand filtration: "*This aspect is of practical significance by virtue of its action in removing organic matter which, in places beneath the upper surface accumulates as films around the sand grains. The removal of organic matter by oxidation and nitrification appears to be a factor in causing indirectly the death of bacteria, which are mechanically arrested by the adhesive action of the sand grains. By some it has been claimed that the bacteria go into a gelatinous form, the zooglea stage; and being attached to the sand grains, they facilitate thereby the removal of bacteria in the active vegetable stage, and of minute suspended particles by means of adhesion.*" As to the

varieties of bacteria in sewage we may gain some idea from the fact that Fuller differentiated 27 distinct species of bacteria in the Ohio river water, which, if pumped, would subsequently pass into the sewers carrying in addition all additional micro-organisms picked up by the water in its manifold uses in a city. There were in addition 64 other microscopic species, including diatoms, fungi, infusoria, etc.

From this summary it will be evident that, given organic matter as food, and the many varieties of microscopic beings present in it, we have only to allow nature's vital processes to go on unchecked, favouring them further as we may in various ways, and we shall find that all or many of such organisms, as indicated, will, by their multiplication, feed upon the organic matters in sewage and thereby reduce it to its simpler elements. We may thus further understand how, for instance, quick lime added to sewage in quantity, being an active germicide, would be likely to notably retard such biolysis, while the creosote and carbolic acid products from the tar of gas works, the tannic and other acids from tanneries, with arsenic and other chemicals, might equally prove extremely fatal to these processes of purification of sewage by natural processes.

Assuming, however, that these various causes detrimental to biological processes are dealt with specially on the premises where they are created, it will be apparent that as no living organisms of any two species have exactly the same life processes that at various stages in the reduction of sewage to its simpler constituents the environment will become more favourable to the activity of this, then more favourable to the other organism. Such indeed has in practice been found to be the case, and the most recent practical methods for dealing with sewage by bacteriolysis or biolysis have been adopted with a view to favor successive series of biological processes by different micro-organisms. Mr. Scott-Moncreiff thus arranges the sequence of acts in the biolysis of sewage: (1) The process of purification by biolysis is not instantaneous but gradual. (2) Dividing it into any convenient number of stages or periods, each of these must represent a different character of food supply. (3) No one kind of organism is capable of flourishing in all the different media or stages equally well.

It must be apparent that given a knowledge of the several stages and of what normally takes place in them, much may be done either to accelerate, or to retard the work, or even reverse the natural order of biological processes. As we have long known in the filtration of water supplies, it has been a comparatively easy thing to remove suspended matters, but a very difficult thing to remove those in solution. Mr. Scott-Moncreiff now, however, makes the assertion *that the process of throwing organic matter into solution was even more easily carried out than that of getting rid of the suspended matters*—formerly removed mechanically and by the addition of precipitants.

He further states *that the question altogether hinges not upon the amount of the organic matter in solution, but upon its instability and susceptibility to further and rapid changes in the direction of complete mineralization.*

To illustrate his meaning we can best do so by referring to his experimental filter. He constructed a filter (see diagram) 2½ feet wide, 10 feet long and 3 feet deep at deepest part. This received the entire sewage and wastes of a household of ten persons, excepting the grease, which is held back as far as possible by a grease trap. The liquid rises through a grating, and then through stones till it reaches an overflow pipe. The filtering materials are only 14 inches deep. He found in different installations of the apparatus that practically complete liquefaction of the organic matter could be obtained, and that the amount of sludge remaining amounted to almost nothing. It may be stated, as I have learned with a filtration tank operating now for ten years, that the same decomposition of organic matters is effected in a covered tank, with the overflow pipe draining off the fluids half-way down in the tank. At the end of the year the sludge remaining does not amount to over a few pounds, grease, paper and other vegetable fibres being broken up almost equally with the sewage. The final disposition of this liquid sewage in this case has been by sub-surface tiles. Mr. Scott-Moncreiff pushed his experiments to determine how rapidly and most simply the further decomposition of this material could be carried out. He found

DIAGRAM ILLUSTRATING EXPERIMENTAL TANK OF W. D. SCOTT-MONCRIEFF.

when this effluent went into a stream that while with the chlorine constituent as a measure of dilution, the latter was as 3 to 1, the loss of albumenoid ammonia was as 7 to 1, or in other words was very rapidly oxidized in the stream.

What was apparent then was that so far the oxygen in the water had first been utilized by organisms in the oxidizing process in the sewer before the sewage reached the tank and that afterwards other anaerobic organisms continued the work, utilizing all the combined oxygen of the organic matter itself. Mr. Scott-Moncrieff thereafter devoted himself to determining conditions most favorable for pushing the process of decomposition of nitrogenous matter still further. To this end a series of nine boxes, each filled with coke (inch size) to a depth of 6 inches, was arranged one above the other, and by an automatic tip tank the top received sewage pumped from the tank which passed successively through the nine boxes 6 inches apart. From under each a series of test samples could be taken at any time. The apparatus was kept constantly working for the three months to test the tendency to clogging of the coke. With the effluent running at the rate of a little more than 1,000,000 gallons per acre analyses were made by Dr. Rideal. The table of results is most remarkable as illustrating the same process which went on in the disintegration of barnyard manure, in other words the oxidation of nitrogenous products as seen in reduction of nitrous nitrogen from 0.99 in first tray to none in trays 10, 11 and 12 and of the increase of nitrates from 0.096 in first tray to 9.0 in tray 12. This remarkable conversion of products occurred in rather less than ten minutes showing the marvelous rapidity of the process.

Now by transposing the trays so as to upset the natural survival of the organisms in the different trays in the sequence, the whole process was arrested, a high colored and inferior effluent being the immediate result, and one or two days were required to re-establish the condition which had been disturbed.

Such then are the experimental results involved in sewage precipitation. As regards these results from the chemical standpoint there have been really two steps, first the attacking of the organic matter alone and second the breaking down of the ammoniacal nitrogen formed, it being changed finally into nitrates by oxidation.

Prof. W. E. Adeney, Royal University of Ireland, calls the two stages, those respectively of carbon-oxidation and nitrogenous-oxidation, and finds that the first stage is complete before the commencement of the second. From this it would appear that the stages of the process are the same in the purification of sewage whether or not the aerobic treatment takes place in the same filter where anaerobic action goes on or in a filter after the previous anaerobic process in a closed tank as that described by Mr. Scott-Moncrieff and now commonly called the septic putrefaction tank. Remembering, however the presence of oxygen in a natural water and that the air of properly ventilated sewers contains it in abundance it will be apparent that the aerobic stage is necessarily present in sewers before the sewage has reached the sewage works at the outfall.

The application of the septic tank principle to the purification of sewage on a large scale as at Exeter, England, is that illustrated by the diagram of the Scott-Moncrieff tank, wherein the entire sewage is submitted in an air free dark space to the liquefying action of anaerobic bacteria, a process daily seen in the laboratory test tube when gelatine culture media are liquified by microbes beneath the surface. Indeed Dr. Sims Woodhead has found that in 1 c.c. of Exeter crude sewage there were one million organisms which were anaerobic and five and a half millions which were aerobic. Of the 1,000,000 anaerobics 300,000 were found to be liquefying organisms and of the five and a half aerobics 500,000 were liquefying. From these, as may readily be seen in the laboratory, are given off carbonic acid, ammonia and other volatile gases. The Exeter septic tank has never been cleaned out, yet rags, paper, straw, feathers are gradually liquefied. Chemists have indeed found and named special ferments which attack and destroy cellulose both in the intestines of animals and in laboratory experiments. Further we have the specific microbe termed *B. amylobacter* always found in putrefying processes and attacking or hydrolysing sugars, starches and cellulose and producing as by-products butyric acid and hydrogen and is essentially anaerobic. The chemist, Mr. S. Rideal, London, has

Table showing successive stages of Mineralization by Nitrifying Organisms. Ashstead Experiments, February, 1898.
By W. D. Scott Moncrieff.

Colonies of Aerobic Nitrifying Organisms.

found that 2 to 3 parts of organic carbon in 100,000 parts of sewage are daily oxidized in the Exeter septic tank and removed in solution as carbonic acid as well as being given off into the air of the tank. Again Mr. Rideal points out, in the septic filters installed by Mr. Dibdin, where the sewage is pumped directly on to coarse burnt ballast of four feet in depth and allowed to stand two hours, to be thereafter drawn rapidly and completely off, its place in the pores of the filter being immediately filled with air to complete the disintegrating process by aerobic action, that the primary stage of *resting fluid* of sewage is an essentially anaerobic or septic stage. It will be apparent that there is equally the condition in the process of ordinary sand filtration of water. We may state then in general terms that any form of rough filtration removes a notable amount of suspended sewage matters amounting, according to Rideal, to about one-third of the organic nitrogen and one-half the carbonaceous matter of the sewage. The Massachusetts experiments as also those of Mr. Scott-Moncrieff point out that such rough filtration even at a very rapid rate as over 1,000,000 gallons per acre in practice removes a small amount of the soluble organic matters. The extended Massachusetts experiments further point out that such rapid filtration effectually removes germicides such as the soluble salts of arsenic formed by adding lime to sulphite of arsenic utilized in certain tanning processes, by the formation of a double insoluble salt of iron and arsenic, thereafter allowing the purification of the sewage to go on naturally by the processes of fermentation through carbon oxidization and nitrogen oxidization.

Summing up then the processes which the sewage of any town would be subjected to, according to what is now known of its treatment, whether mechanical, biological, or chemical, we would have

1. An initial aeration as in water and in the sewers, causing the production of a certain small amount of nitrogen, as free ammonia, to be present.

2. For the treatment especially of sewage including industrial wastes, and inorganic refuse as clay and sand, a rapid filtration through a bed of coke or coal, moderately fine over coarse, the upper layer of which can be readily removed and burned, the filter working at the rate of 1,000,000 gallons per acre daily, for a considerable time without clogging, or if the sand and clay have been in large part removed by previous sedimentation, at the rate, according to the late Col. Waring's experiments at Newport of 3,000,000 gallons daily per acre. The process in both cases removes from forty to fifty-four per cent. of albumenoid ammonia in the sewage.

3. The passing of the sewage upward through a second coarse coke filter, which may be termed the septic tank, or the alternative method of allowing the sewage to rest on a coke filter for several hours before draining it off.

4. The final passage of the sewage over a sand filter, a coke bed or to a sewage farm, where by aerobic fermentation the final reduction of organic nitrogen, as soluble free and albumenoid ammonia will take place by nitrosification and final nitrification

*We have seen in the table given in connection with Mr. Scott-Moncrieff's septic tank experiments the amounts of organic nitrogen in the effluent from the septic tank, and the nitrites and the nitrates after filtration through the successive coke filter trays; but the following analysis is of sewage taken January 3rd, 1898, from the Exeter works:

Analyses of Raw Sewage and Tank Effluent.

	Total solids.	Parts per 100,000.			Nitres.	Chlorine.
		Free ammonia.	Albumenoid ammonia.	Nitrites.	Nitrogen as nitrates and nitrites.	
Sewage, 4.45 p.m.	63.0	1.60	0.48	Nil	Nil	5.6
Septic tank effluent, 4.40 p.m.	65.6	4.00	0.25	Trace	0.13	6.3

Filtrate, filter 4, five minutes after discharge.	62.5	0.20	0.09	Nil	2.00	5.5

* See Table, page xxxiii.

Having thus in the several paragraphs dealt with the principles involved in sewage purification the question will always arise with our municipalities and their officers as to the practical methods by which such principles can be carried out. If we were to sum them after our own observation and study it would seem that the following conclusions are justified in practice :

1st. Reduce the town sewage to be treated to a minimum (a) By the metering of the household supply of public water; (b) By the introduction of the separate system of sewers; (c) By the laying of open tiles in the same trench but at a little lower level than the sewer for dealing with ground water.

2nd. Lay all pipes on best gradients possible and thereby conduct sewage to its outfall as rapidly as possible.

3rd. In all cases where street wash, as in combined systems, is allowed to reach the sewers, have street catch basins, also have conical bottomed tanks at end of outfall sewer to catch the sand and other mineral or heavy deposits.

3rd. Have sewers laid with a view to discharging the sewage, with the least possible amount of pumping.

4th. In all cases conduct sewage into a tank at outfall capable of holding the greater part of a day's supply of sewage, this tank being in fact a septic tank of coarse coke, arranged preferably as a pair, the sewage discharging either on to the coke or from below upward. By the alternate tank and surface discharge the removal of the surface layer of coke is readily accomplished.

5th. The passage of the effluent from the septic tank preferably, if possible, to a sewage farm, where the utilization of the nitrogen compounds would produce the highest economic results without any possibility of a nuisance. This latter method is exactly that adopted ten years ago by Col. Waring in the disposal of the 75,000 gallons of sewage of the London Asylum with its 1,200 inmates. It is simply the collection of the sewage from all the buildings into a covered brick tank, whence the sewage is pumped daily a quarter of a mile and there distributed by the flat bed system in ditches to a porous sandy soil, and from which the water is rapidly utilized in watering the vegetables in the intervening flat beds. The value of these crops in the area of a four acre farm is estimated at least £200 per acre.

6th. When owing to the price of land or its impermeable character this method is not wholly available, the final nitrification of the sewage from the septic tank will best be completed by a series of coke or sand filters through which the sewage will be allowed to pass slowly and intermittently, the tanks being used in succession.

We have very briefly summarized what seem to be the main biological facts involved in the complex problem in the dissociation of the organic compounds contained in sewage, and the natural processes by which such materials are reduced to simple compounds in what has been called by Professor G. Sims Woodhead, the mineralization of organic matter. He thus expresses himself :—

“ It would appear in fact as though there were developed special organisms for the setting up of special fermentations, and also after the breaking down has been carried a certain length by one organism, the aid of another is invoked to complete the process more thoroughly and more expeditiously. We have in this, as in the case of the process of digestion, an exemplification of the fact that nature economizes her resources as much as possible : she does not call on the animal cells of the alimentary tract to do the work that can be equally well done by micro-organisms, nor does she demand the exercise of more than one or two functions from each of the protoplasmic specks that we call bacteria. To each one is assigned its special work, and though it is possible that many of them started with certain powers in common, it seems that through the exercise of some of those common powers under special conditions they have become differentiated functionally, that, as amongst organisms more highly developed, each is able to carry on its own work best at those special stages of the putrefactive process at which it is found. It might at first sight appear that all this can have but little bearing on all practical work in which we are engaged, or in which we take an interest, but on more careful consideration it will be found that these putrefactive organisms really keep up the circulation of matter, utilizing the excretions of living beings and the carcasses of dead animals and plants, after

breaking them down into their simplest constituents, to supply those elements that are necessary for the nutrition of plants, allowing them to present themselves in their most assimilable forms, and in the proportion most suitable for the nutrition of the growing, highly organized vegetable protoplasm. Bacteria in fact serve to transform inert organic matter into organic substances. This transformation or 'mineralization' in most cases commences when protoplasm has lost its vitality, and most micro-organisms are capable of attacking this dead protoplasm only; though, as we shall find later, a certain number of bacteria have acquired the faculty of being able to attack even living protoplasm. The process of decomposition may be divided into two kinds: first, those going on as the activity of organisms that are capable of taking up their oxygen from the air, and, second, those the result of the activity of organisms that so break up and re-arrange the organic molecules containing oxygen, that not only do they, the bacteria, take up oxygen themselves, but they allow of its being handed on to the product, to which in their processes of metabolism they give rise. It is probable that here we have to do, not only with nascent oxygen, but that we have certain products set free during the process of decomposition which seizes upon oxygen with very great avidity. This decomposition or re-arrangement is spoken of as a process of nitrification or a conversion of the nitrogenous elements into ammonia, nitrous and nitric acids, carbonic acid and water, or speaking more generally, it may be said to be a process of mineralization of the organic forms of nitrogen, phosphorus, carbon and hydrogen, during which they become finally oxydised or mineralized to nitric acid (HNO_3), phosphoric acid (H_3PO_4), carbonic acid (CO_2), and water (H_2O). In nature this process goes on in the superficial layers of the earth or in the presence of the atmosphere. That it takes place much more readily near the surface of the ground and in porous earth can easily be understood, if what takes place in the oxidation that goes on in spongy platinum is borne in mind."

So much appears in this problem viewed wholly from the sanitary standpoint; but it cannot be supposed that any natural processes involving the mineralization or reduction to a condition available for plant food of the enormous amounts of organic wastes from human populations can be accomplished without involving other scientific and sociological principles. This is illustrated by the fact that, dealing only with a single country, the population of England imports annually about 120,000,000 bushels of wheat, or to take the problem of Sir William Crooks in his presidential address before the British Association for the Advancement of Science, in 1898, he has stated that the "bread eaters of the world have increased from 371,000,000 in 1871, to 516,500,000 in 1898," and has calculated that in order to give each an average daily amount of food 2,324,000,000 bushels annually are required. This remarkable advance in the amount of food supply required is illustrated from the further standpoint, that the population in 1891 of 68 towns in Germany, England and France, together included 21,050,000, while in 1840 there were but 4,800,000 persons living under similar conditions. A recent writer regarding trade and commerce, has made the further remark that the industrial population to which Manchester is the importing and distributing centre alone amounts to some 10,000,000. It is hardly necessary with such facts before us, to point out that since the equivalent of every bushel of wheat is represented in the sewage wastes of our cities and towns by a definite amount of organic nitrogen, the problem is a serious one as to how long the indiscriminate destruction and waste of this natural food for plants, and especially for the wheat crop, by allowing the sewage to be poured into the streams, can go on, before there will be a natural scarcity of that nitrogen upon which the success of the wheat crop most intimately depends. This matter has been dealt with recently by Sir William Thompson, Lord Kelvin, in which he has pointed out the startling fact that the United Kingdom sends annually to the sea nitrogen to the value of no less than £16,000,000 sterling.

Professor Crooks further points out that the sources of artificial fertilizers, such as nitrate of soda and guano, are rapidly becoming exhausted. And he states, further, that while the storing of nitrogen in the atmosphere is practically unlimited, it is, nevertheless, rendered fixed and assimilable only by cosmic processes of extreme slowness. "The nitrogen which with a light heart we liberate in a battleship broadside, has taken millions of minute organisms patiently working for centuries to win from the atmosphere." He then refers to the question of what other sources we have to look to in order to obtain the nitrogen without which the growth of the food of man becomes an impossibility; and then refers to experiments by which it is made apparent that electrical oxidation of the nitrogen of the air is likely sooner or later to become a commercial source of supply of artificial fertilizers for the growth and development of our food supplies.

These references to the discussion of such important problems by two of the greatest of the world's physicists is enough to cause us to carefully study the conditions prevailing in Canada in order that we may at any rate limit by prompt action the mistakes already made and which have become so serious in the older countries of Europe and Asia. We must fully realize that there is not only a unity of purpose in nature's processes, but also that all the forces of nature have an intimate relationship with one another, and that as all forms of animal and vegetable life are dependent upon inorganic life, so inorganic matters are again reproduced by the disorganizing, dissociating processes of plants and animals. We have already seen that the amounts of organic wastes from any given population, calculated as to their value from a fertilizing standpoint, can be accurately estimated, and that there is only the problem remaining of the invention of mechanical methods by which biological processes can be made available in a commercial manner by turning such wastes back again into plant foods. As already stated in the beginning of this chapter, the problem has scarcely been touched in Canada, but necessity therefor has hardly been realized, and the municipal methods have been hitherto much too crude to enable any municipality to adopt comprehensive measures for successfully carrying out from the commercial standpoint nature's plans for the turning of the organic wastes of town sewage into artificial fertilizers. What can be done has been well illustrated in certain places in England, and still better at Paris and at Berlin. We have too in Ontario one illustration of how sewage may become an actual source of agricultural wealth, viz., that of the sewage farm at the London Asylum; but as yet it is but a beginning.

The city populations have not yet been great enough, and the diluting powers of our lakes and rivers have been too large to heretofore force problems, such as the conservation of the wealth contained in the nitrogen of sewage, upon the attention of our people. The city now only thinks of getting rid of these wastes at a minimum of inconvenience and cost to itself, regardless largely of whether it does a material or vital injury to its neighbor. The agriculturist has too inadequate an idea of the loss he yearly sustains through the removal of nitrogen products from his farm, as straw and hay, to seriously question whether the sewage of towns has any settled relation to his commercial success. Under such circumstances, it is quite clear that the notable evolution of scientific thought is necessary amongst our people before they can realize that the producer and consumer of foods have commercial relations quite as intimate as are either their political or social relations, and we have yet to learn and put in practice the truth contained in that very ancient story of Roman history in which Menenius Agrippa convinced the common people at the Sacred Mount how intimate was the relationship between the ruling class or the patricians, and the common people or plebs, by the memorable fable of "The Belly and the Members."

As however, the nineteenth century has seen made year after year discoveries each seeming to surpass the other, so we have every reason to believe that the scientific evolution of the twentieth century will be adequate for the social needs of generations to be. With the powers given under public health laws in Ontario we only require the steady advance of public opinion through education, and an increasing realization of the belief that each unit of society influences definitely the well being of all others to see a balance more than maintained of the constructive over the disintegrating forces which affect society at large. Such a belief is that given expression to in the closing words of the late Sir John Simon in an address on "Experiment as a Basis of Preventive Medicine." He said: To the science of nature, indeed, is allotted that one incomparable human day which knows no sunset. In the fierce light of its everlasting daybreak individual workers will pass away, generations will change; but the studies of nature and above all, the gathering of such knowledge as can lessen man's physical difficulties and sufferings will surely grow from age to age, and, as in Proserpina's sacred tree, one golden fruit will follow another:—*Simili frondescet virga metallo!* Such were the enthusiastic words full of faith not only in the future of Preventive Medicine, but in the happiness which would accrue therefrom to men, spoken (in 1881) by the great leader of Preventive Medicine. And yet, reviewing the situation at the end of the century, we are forced in the words of Dante to say:—

"There is no light that comes from the Serene
That never is o'ercast."

Self interest, ignorance and prejudice have delayed, and will still prolong the struggle of man upward to the light; but in the words of Dr. Crozier :—"The scientific spirit is already a potent one, and is daily exercising more and more influence over the most intelligent and cultured minds." Philosophers of all ages and in many lands have seemed to see in the near future the realization of their dream when as with Buddha evil would be banished and the higher nature would be supreme at every point where man would "stand like a pillar of the city gates unmoved, like the broad expanse of earth unveiled, or like the pellucid lake unruffled." But the dream is far yet from being fulfilled; and nowhere is it more frequently or more painfully forced upon us than while endeavoring to obtain some comprehensive idea of the manifold influences affecting man unfavorably in regard to his physical environment, and through this his whole intellectual and moral nature. While it may be quite true that man knows better than he does, yet the fact stands, that he would require "a complete and perfect knowledge of physical, mental, moral and social laws," were he to be able to banish all the ills which flesh is heir to, and which we have already amply illustrated is far from his present position. And yet it is sufficient to urge us onward in the work that lies before us to believe and remember the immortal words of Tennyson :—

"A soul shall draw from out the vast
And strike his being into bounds
And moved thro' life of lower phase
Result in man, be born and think,
And act and love, a closer link
Betwixt us and the crowning race.
Of those that eye to eye, shall look
On knowledge; under whose command
Is earth and earth's, and in her hand
Is nature like an open book."

Respectfully submitted,

P. H. BRYCE, M.A., M.D.,
Secretary.

PART II.

CHAIRMAN'S ANNUAL ADDRESS.

By J. D. Macdonald, M.D., Hamilton.

TORONTO, January 30th, 1899.

GENTLEMEN,—It is, I think, my duty, and if it be not my duty it is my impulse, to give expression to my satisfaction at our meeting here again at this time to begin the work of another year and that all our associates are in the enjoyment of good health and ready to perform the functions looked for from them as members of the "Provincial Board of Health." It is not unusual to speak of transactions such as we are to engage in as "labours." I do not use that term in connection with them. They are of so much interest to us all, that I am persuaded it would not be truly descriptive if they were thus distinguished.

It was at one time thought, on the part of some, that this meeting would not consist of the same members constituting it hitherto or at least for some years past. It is I think proper for us to say that we think it to be well that no change, such as may have been expected, has taken place. The duties of the Board are such as to make it desirable that one of its characteristics should be its continuity, such changes as take place in its membership not involving all those who composed it at the same time.

In opening our meeting for the year, it is a pleasure for us to say that the health of the country has been good during the year which has passed. No epidemic has appeared, nor have infectious diseases obtained a footing in the land. Some of the latter kind have appeared, as appear they will from time to time, but whenever such have caused alarm so as to cause that they be reported here they have been promptly suppressed by measures directed by the active secretary of the Board. Diseases of that nature are seen tabulated in the monthly reports, but the cases have not been so numerous as to enable us to say that they have had any prevalence. Hitherto however an exception should be made with respect to our old enemy tuberculosis. It is always present, a persistent life destroyer, and during the year past has been true to its history. It has cost the country more lives than all the other diseases reported when added together.

Tuberculosis hitherto has been less influenced in its prevalence by endeavors at prevention than all others of the infectious maladies. To the mind of the medical profession its continued virulence is due to the chronicity of the disease and hence to the difficulty in the use of such means towards checking its diffusion as are serviceable in other infectious maladies whose course is shorter. It is not altogether too strong language if we say that the profession is in a vexed state because of the difficulty of bringing about some degree of suppression of this malady, and that not because the difficulty is insuperable, but because so far society has not come to look on the necessary means with favour. The means are regarded as too severe and as being to "the many" altogether unpracticable.

Notice is before us, for discussion to-day, on the part of our confrere Dr. Cassidy, of a paper whose purport it is that the Board declares phthisis to be a notifiable disease. Placarding a house is spoken of by the laity with impatience. Most of us are aware that this is a thing to be desired. We have discussed the matter with the profession and with our friends outside of it, and the result has always hitherto been that the project has been dismissed as being one which would not be tolerated. To keep a house quarantined and denied social intercourse for a year or two as it might be, would seem a severe infliction, and it is more than doubtful if either the inmates or their friends and neighbours would give attention to the warning left by the health officer. Very many consumptives continue breadwinners for years. For such the inhibition placed upon the door would be a hardship, and would be regarded as an unreasonable interference with the duty of earning the daily bread of the family. Some of us who have discussed this expedient for the prevention of disease with our friends and acquaintances have had the matter presented to us in the light just adverted to and that with some touch of indignation as if the measure was high handed. Upon the whole it would seem that much time will be needed to reconcile the majority to such a decision on the part of the Board of Health.

The other mode of separation of the tubercular from the healthy, to wit, that by means of consumption hospitals or homes, meets with less objection. It seems acceptable, especially to those whose worldly circumstances are comfortable and who expect to pay for their residence and treatment in those institutions. No one says anything unfavorable of them, and as is well known they are very generally taken advantage of. Those accepting the benefit of them are the comfortable classes, and where pecuniary conditions permit they are most beneficial institutions. If it were possible to get the labouring classes accommodated in such the problem of the prevention of phthisis would be nearer its solution. In the meantime, however, the larger number of those affected with phthisis are necessarily excluded from them, and will continue to be, unless the providing of the hospitals be undertaken at the public expense, whether on the part of the Governments of the Provinces, or of the municipalities.

It seems to be believed by many whose opinions are of value, that a principal agent in initiating tuberculosis in the human subject, is the bovine family. Perhaps if that family had been able to entertain and express an opinion, we might be given to understand that the course of things was, probably, at least often, the reverse. But there can be little doubt the treatment of cattle, the habits of life imposed upon them, is very favourable to the lodgement and increase of the bacillus of tuberculosis in and among their tissues. It is very likely that many a family, both in town and country, when phthisis breaks in upon them need not have to look farther than their cattle stables when they ask for the source of the plague which has cost them so dear. The evil here adverted to, it has to be admitted, is not overlooked by health authorities, but there can be no harm in impressing upon the owners of cattle, both for the sake of their own health and of that of others, that they be particular about the cleanliness and free aeration of their premises, and that health authorities throughout the country be frequently exhorted to increase their watchfulness over the district committed to their supervision. For the rest, much may be trusted to the gradual growth in the public mind of the necessity of consenting to measures for the restriction of consumption which may seem to them now to be excessive. The general acquaintance with the nature of the disease has increased much within the memory of some of us, and no doubt will grow more towards perfection.

AN ARGUMENT FOR THE APPOINTMENT OF COUNTY HEALTH OFFICERS.

Quarterly Report of the Secretary.

TORONTO, April 19th, 1898.

To the Chairman and Members of the Provincial Board of Health :

GENTLEMEN,—Inasmuch as the Act establishing Local Boards of Health in Ontario has been in operation for fourteen years, it has appeared to your Secretary proper to present for your consideration the results of his experience in the operation of the Act in effecting the objects for which it was established, as well as some statistics gathered from a circular sent out to Medical Health Officers, dated February 15th, 1898.

It will be remembered that up to 1884 there were only a few health committees of municipal councils in existence, and that before that time whatever public health work was done was rather of an accidental character, as when some outbreak of small-pox demanded special attention. Since 1884 public health work has been by law relegated to local boards of health, formed of ratepayers, who might or might not be members of council. Up to 1895 many of such boards were composed largely of the members of the council, but I find in the answers to the circular that owing to the amendment to the Act in that year making the term of office three years for the appointed members, boards are

now generally composed of the ex-officio members (the reeve and clerk of the Council) and ratepayers who are non-members. This is reported to be the case in 169 of the 285 replies received.

There is evidence to show that this result has served to make the Local Boards more independent in their actions than formerly, but that their operations are still in most instances of a very limited character is shown by the replies stating that in very few instances, comparatively, is any grant placed in the estimates of the Municipal council at the beginning of the year for public health work.

Thus from 285 replies it is stated that 16 boards in cities, towns and villages have grants to the amount of \$51,374.00, more than half this amount being for the city of Toronto; and that 13 boards in townships have an amount set apart equal to \$560.00. Speaking generally the answers state that the boards send in their accounts to the Council, which are not always passed, at least without serious discussion.

That the amount that is expended, except in the case of the larger cities, is insignificant may be gathered from the tables following. With regard to these amounts for public health work it is, however, of further interest to note the replies made to the question as to whether members of the Local Boards receive any allowance for meetings of the board. From 285 replies it is found that in accordance with the practice as regards the Council no payment is made to members of city and town boards; but as regards township boards it will be seen that 106 out of 243 boards receive a per diem allowance for attending meetings of from \$1.50 to \$3.00, with, in some instances, mileage. These amounts are not included in the amount stated in the instances given as being set apart for the work of the year.

In connection with this allowance to members of the board the answers to the question as to what amounts are paid and how to the medical health officers of the boards may be noted. From the 479 medical health officers appointed for 1898, 285 answers were received. These answers are summarized in appended tables.

Under the Act, however, provision is made for the appointment of sanitary inspectors. According to the returns of boards organized in 1898, 150 sanitary inspectors were appointed. Replies regarding these appointments and salaries were made from 285 boards. The answers summarized give the results seen in the tables.

Such then, so far as statistics are available, are the results of fifteen years' evolution of public health work in Ontario. It must be remembered that there are some 745 organized municipalities including those in the Territorial Districts, most of these latter, however, having populations averaging probably 500.

For 1898, 568 boards have been reported as having been appointed by the Councils. Of these reported, 479 have medical health officers appointed, and 150 have sanitary inspectors. Of the replies made to the circular 204 or 71 per cent. state that the medical health officers are appointed annually, and 28 or 10 per cent. during the pleasure of the Council. Of the same number reporting, 70 per cent. of the sanitary inspectors are appointed annually, and 10 per cent. as per reports during pleasure or permanently. Of the boards appointed, 40 per cent. in townships pay a per diem allowance to members of boards, 60 per cent. pay nothing.

Of the medical health officers, 30 per cent. receive an annual salary, 60 per cent. are paid only for such specific work as they are asked by the Council or Local Board to perform, and 2.0 per cent. receive nothing, except as remarked by some, "glory."

While we must remember that the Public Health Act has been in operation but 15 years, while it cannot be forgotten that public health work everywhere has practically a history of but half a century, and that in Ontario a very notable number of municipalities have been organized within this period, yet it must be confessed that the results so far as the organization of an effective and systematized public health system in the Province is concerned are somewhat disappointing, though not discouraging. They are not discouraging for the following reasons:—

1st. That the work was 15 years ago, one whose needs and aims were unknown practically to the great body of the people. The mass of the people thought disease had to be, and that they should endure it with resignation.

2nd. That to-day a very general public opinion has been developed, to the effect that a notable number of our most fatal diseases are communicable by contagion from person to person; that others depend directly on insanitary conditions as polluted water, and wrong sewage disposal and that therefore both are preventable.

3rd. That private and personal interests in matters of health must be made secondary to the greater public good.

4th. That daily from every direction, we have evidences that the people generally show a remarkable willingness to obey the laws for promoting the public health, often to their own personal or family inconvenience.

5th. That constantly from private persons and from officers and members of health boards, appeals are made to your Board, and local authorities for the enforcement of law.

6th. That the Legislature and Municipal councils have made abundant provisions by specific enactments for dealing with almost every kind of insanitary condition.

Wherein, therefore, would seem to be found the reasons for results, which it must be confessed are disappointing?

I do not propose to enter upon a discussion of the merits and demerits of our system of municipal government, but shall refer briefly to such points as bear upon the subject in hand. Much has been said for and against the powers given to school authorities to demand such amounts of municipal moneys as they deem requisite for maintaining and promoting educational progress. Since trustees are elected by the people, they would seem to be as directly responsible as members of the Councils for the expenditure of public funds. As Local Boards of Health are appointed and not elected, it may fairly be argued that they should not at will have the power to make expenditures for which they are not directly answerable to the people. Inasmuch, however, as they are required to perform certain duties positively laid upon them by the Public Health Act, it is apparent that where the Councils fail to make grants, the work must either be left undone, or the board must have a right to call upon the treasurer to honour their bills. Such indeed is actually the law; and it might be assumed that Local boards would take advantage of their powers. As a matter of fact however, as we have seen from the returns, Local boards have been so tied up in their membership with members of the Council, that they have but seldom realized and asserted their rights and powers.

This same neglect to exercise legal rights and duties has operated yet more in the case of medical officers. Though the Public Health Act distinctly empowers and requires such officers to perform many of the same duties, which are required of Local boards, whether or not the latter order the same to be done, yet by an anomaly of the Act, the medical health officer is an appointee of the Municipal council, and as we have seen is practically always appointed annually. It is plain therefore and has proved almost invariably true in practice, that any medical health officer who has actually attempted to carry out the duties he is called upon to perform by virtue of his appointment has antagonized the Local board, which, in practice, seems to think that it has the sole right to determine what a medical officer ought or ought not to do. Should such an officer, however, attempt to do thorough work, and be supported by the Local board, he will soon find that since he is the appointee of the Council, they will see that he shall not a second year incur expense in carrying out the plain intention of the Act. They have, however, insured that such an officer will not prove too active by limiting his salary, if indeed he receive any at all, to such an insignificant sum, that no medical officer for the amount paid is likely to make himself antagonistic to the Council and make himself unpopular with the people amongst whom he practices. Just imagine such an officer seriously attempting for the \$5.00, \$10.00, or \$25.00, the average annual salaries in all but the towns and cities, to do public health work, oftentimes thereby creating misunderstandings

with his fellow practitioners, and offending those (who may violate the law) and yet may be or are his patients.

The experience of fifteen years has abundantly illustrated the fact, that while the Local boards are in a position to do good work, the method of appointment, the tenure of office, and the salary or fees paid, make the position of the medical health officer an anomaly and absurdity. We except, of course, the large cities, where a certain importance and dignity are attached to the office, because of the extent and urgency of the work, and because the salary is at times enough to cause an officer to give himself loyally to the work.

The position of a medical health officer of a township is especially an anomaly, for there we see five members of a board of health holding from six to twelve meetings annually, at a cost of usually \$10.00 a meeting, often with mileage, or say \$100.00 a year, and who, when in their wisdom they think it convenient, call in the medical health officer, generally to do some disagreeable work they do not wish to touch themselves, and then offer him a fee, perhaps not greater than each of themselves receives for sitting upon the case.

There are two other good reasons why the present system cannot progress. First, because sanitary work is largely scientific work, and members of Local Boards of Health do not understand how to effectively deal with the troublesome technical matters that are frequently arising, and second, because the extent of the work in a single small municipality is too limited to enable it to pay a medical health officer for devoting such time to the work as will make him conversant with all the phases of public health work, or be willing to antagonize persons whose selfish interests he may affect.

To illustrate this point, I may mention the facts again and again brought to my attention by those interested in cheese factories, viz.: that Local Health Boards or their officers have failed either to suggest or enforce measures for remedying the nuisances so dangerous to the manufactured products, caused by the disposal of the refuse from these factories. Your secretary has been appealed to to have special Provincial powers given to the inspectors of cheese factories. Similar appeals have been made to obtain Provincial powers for inspectors *re* tuberculosis in cattle. Appeals have again and again been made to have Provincial inspectors appointed by the Government, though, as we know, there are now five Provincial inspectors dealing with the inspection of factories.

Obviously then, the object of the Act in the appointment of Local Boards of Health for the ordinary small municipal areas, but especially for the development of scientific sanitation through medical health officers, has failed of its accomplishment. No physician conscientiously desirous of doing good work will, or can be expected to, place himself in a position so anomalous and undignified as the instances quoted show it to be; and hence we have now to enquire whether after 15 years, during which the science of Preventive medicine has grown so marvellously in exactness and the certainty of the methods to be adopted, there is not another means by which, with the expenditure of even less public funds, results can be obtained commensurate with the outlay and in keeping with scientific advancement in other fields of public work. Manifestly there are three conditions necessary to accomplish the desired end.

First.—Enlarge the area of the sanitary district to such an extent that it can afford to pay adequately for the services of a medical health officer, who shall devote all his time to the work.

Second.—Ensure the training of men in the various branches of applied science necessary to fit them to perform well the duties of a medical officer of health.

Third.—Permanency of tenure of office.

Dealing briefly with the first, it may be said that the electoral divisions, or the districts for which county inspectors of schools are appointed, would be amply large enough to give to a single medical health officer the very fullest occupation.

As regards the second point, men having a science degree in arts and a degree in medicine, would readily be able to fit themselves for the work, and prove their fitness by

examinations specially held on the class of work to be done. There will be no serious difficulty about getting trained men if the opportunities for permanent appointments exist.

As to the third point of permanency of tenure, it is unnecessary to do more than say that, like all scientific work, its very progress demands that medical health officers be kept apart from those questions which seem to-day to almost inevitably drag ordinary citizens within their influence. The man of science everywhere, as in our colleges, cannot afford for the sake of his work to meddle with political questions, and by the same right he may demand that he shall not be made their football, and that in the work of a health officer, where of necessity he must oppose himself at times to selfish interests, the public must insure for him that he be independent in action.

These matters, gentlemen, have seemed to me so important at the present juncture that I would in conclusion respectfully suggest that your Board will use all its influence to have the needs of its work in the matter so strongly set forth that a bill for amending the Public Health Act in this direction may be prepared for submission to the next meeting of the Legislature.

I have the honor to be,

Your obedient servant,

P. H. BRYCE,

Secretary.

The report was unanimously adopted.

Replies to Questions in circular dated February 15th, 1898, and sent to Medical Health Officers.

Question 2.—Is the appointment of Medical Health Officers and Sanitary Inspector made annually? If not state definitely on what terms the Council made the appointment.

(T.=Towns or urban; P.=Township or rural.)

REPORT ON OUTBREAK OF TYPHOID FEVER IN RAT PORTAGE.

August 2nd, 1898.

Report of the Secretary on Contagious Diseases during the quarter.

Mr. Chairman and Members of the Provincial Board of Health :

GENTLEMEN,—By reference to the published reports which are distributed monthly to every secretary of a Local Board of Health and to every newspaper in the Province, you will notice the absolute deaths returned for each of the notifiable diseases.

The returns for July have not yet been tabulated, the law requiring that they be in by the fifth of each month.

The returns made from day to day to August indicate however a continued low mortality, there being but two notable outbreaks of disease ; one of these at Rat Portage, the subject of special report, and the other in Ottawa.

By comparison with the figures for 1897 representing a smaller population it will be seen that the mortality from scarlatina and diphtheria in 1898 is still lower than the low rate for 1897. Measles has shown a mortality though small in the total, yet rather greater than in 1897. It is notable, however, that the deaths in the city of Ottawa from this disease should in July have risen to nine, or more than for the whole Province in June.

It is quite evident that the measures for suppression exercised are wholly inadequate, and it again brings the question before this Board and the public, How are measles to be controlled ?

From information obtained from various sources, your secretary became aware that typhoid fever had again appeared in Rat Portage. In the thirty days preceding July 20th five deaths had occurred, although not returned by the monthly report to the Registrar-General.

Your secretary, with the approval of the Minister of the Department, visited the district and has endeavored to obtain the facts regarding the outbreak.

From the report made to this Board of the outbreak in 1897, it became apparent that there were two principal sources of the disease.

1st. The polluted bay water along the docks which was used by private parties, by employees on steamboats, and pumped to several hotels and other buildings.

2nd. To the use of water from wells so situated as to be almost certain of contamination.

It will be remembered that the Board has approved of a public water supply, which is being put in at much expense, and will in a few months be available for general use, should the town Council and Local Board deal strongly with the question of closing all wells in any way liable to pollution.

The following facts were developed by the investigation :

1st. That five cases occurred in employees on steamboats.

2nd. That five cases (and probably five more) occurred in C.P.R., employees who used tank water supplied from the polluted bay by a steam pump. The second five cases occurred in employees who may have used polluted water at points along the railroad where they worked.

3rd. At least four cases occurred in a large hotel, which pumped bay water by a steam pump.

4th. The balance of cases, some 15, seemed associated with the use of well-water, but from no particular well.

5th. That at least one physician stated that he had attended some 30 or 40 cases of what he called " malaria."

It was most gratifying to have found that no case was associated with the use of Lake of the Woods water as supplied by licensed water-men from above the town.

It was thus apparent that the prohibition of water from every other source seemed desirable, and will be possible when the water works have been completed. In the meantime, a careful personal investigation by your secretary was made of the different sections of the town, and some 40 water samples taken from wells for examination.

Such investigation, showed a town which has developed remarkably under notable physical difficulties, owing to its hilly and rocky character.

Many streets of well-built houses with new ones springing up on every hand are seen, and while there was room for the extensive operation of the new scavenger by-law to go into operation in September, yet Rat Portage, with a public water works and a sewerage system, with the dry earth-closet by-law enforced, bids fair to become, with its splendid Lake of the Woods, one of the most progressive and healthiest towns in the Province. Your secretary in view of the unsuccessful attempt of the Local Board to deal with a recalcitrant owner of a large hotel, felt it his duty to instruct the County Crown Attorney to prosecute under section 29 of the Public Health Act.

The regrettable fact is again made apparent by the returns, that tuberculosis still claims the majority of victims from contagious disease, and shows for June, a mortality equivalent to that of 1897, although the decrease in some centres, has been so repeated for several months as to be notable.

The Province has been free from smallpox, during the quarter, but the unfortunate condition of the Halifax quarantine management, by which smallpox has gone past in two ship-loads of German immigrants, resulting in detention camps for 1,200 persons in Manitoba for the last two months, indicates with the presence of 15 cases at one point in Ohio, that the disease is not dead, but only awaiting an opportunity for spreading again.

It is appropriate that school authorities should take advantage of the season to require certificates of vaccination from all school children returning to the schools in September.

All of which is respectfully submitted,

(Signed) P. H. BRYCE.

REPORT ON SANATORIA FOR TUBERCULOSIS.

November 30th, 1898.

Quarterly Report of Secretary.

Mr. Chairman and Members of the Provincial Board of Health :

GENTLEMEN,—With regard to the Province of Ontario, it may very well be said, that during the past quarter no sanitary subject has loomed up more largely in the public interest than the problem of the prevention of tuberculosis.

1. Thus we have had the monthly Statistical Report, which has given regularly the total number of deaths which the disease has exacted from our people.

2. The subject received special prominence in the discussion both at the meeting of the Executive Health Officers' meeting, and that of the American Public Health Association in Ottawa.

3. We have had reports of the special steps which are being taken for the establishment of the Citizen's Sanatorium and Hospital for Consumptives in Toronto.

4. The published first annual report of the institution of the National Sanatorium Company at Gravenhurst.

5. Communications from the medical officer of Niagara Falls of the general application of the tuberculin test in the county of Lincoln, to cattle.

6. The reports in the newspapers of the proposal for Homes for Consumptives for Ottawa and Chatham.

The newspapers have had published papers, and extended editorials dealing with different phases of these subjects, and your Board has distributed a large number of copies of your Secretary's paper, "On the duties of the Public in dealing with Tuberculosis."

This activity in so many directions indicates most surely, how thoroughly aroused both the professional and general public have become in this problem of problems, which is receiving as great or greater prominence both in Great Britain, on the Continent and in the United States.

This Board may feel that the educational work which it has done, as illustrated by the series of letters, reports and papers published during the last 16 years, has not only spread useful truths amongst the general public, but also, that the organized public health machinery of the county, state and municipal authorities in Ontario is now beginning to give practical effect to what their people are demanding.

To again present in a condensed manner what are the needs of persons in those occupations, which cannot be said to enable families to maintain for any length of time, their sick without great sacrifice, the following table of occupations has been prepared, which indicates exactly, the degree to which different classes fall victims to this disease in Toronto.

Laborers	147	14 per cent. of all Occupations.
Artizans	288	28 " "
Business men (inc. clerks and travellers).....	124	12 " "
Farmers	29	2 " "
Students (18) School children.....	27	.. " "
Professional men (inc. 9 male teachers).....	26	2 " "
Gentlemen	14	1.4 " "
Stenographers, Telegraph and Telephone	15	1.4 " "
Public Officials.....	8	0.8 " "
Sailors.....	6	0.6 " "
Soldiers.....	3	0.3 " "
Convicts	2	0.2 " "
Pedlars	1	0.1 " "

690

Females (only).

Housewives	221	22 per cent. of all Occupations.
Servants	36	3.6 " "
Widows	28	2.8 " "
Milliners and Laundresses	21	2.1 " "
Female Teachers	14	1.4 " "
Nuns.....	14	1.4 " "
Farmer's wives.....	3	0.3 " "

337

Both sexes (under 15 years	737
No occupation given (Female)	395
No occupation (Male).....	105

1,237
2,264

Exclude the following classes of Business men, Professional men, Gentlemen and officials, these being

Business men, which includes 80 book-keepers, salesmen and clerks.....	124
Professional men	26
Gentlemen	14
Public officials	8

172

and the balance (excepting an uncertain number from housewives) or 83 per cent. of the occupations given, belong to those earning a daily wage, and it will appear, how large a proportion of the 2,290 who died within 5 years, an average of 458 annually, are unable to adequately maintain a long financial fight against disease.

How many motherless children are left behind, is seen in the fact of "Housewives" standing prominent as first in the list; and how "Sisters of Mercy" fall victims to this disease in their lives of self-sacrifice, is too truly indicated by the tell-tale records. How many are found from each of the several artisan classes, need not be specially singled out; but what is plain, is that very few indeed in the list are in a position to take advantage of what Dr. Sir William Broadbent, once again points out—"fresh air and fresh air." He has repeated one might say word for word, what we have been teaching for years, and gives illustrations of how such is the only successful method for dealing with tuberculosis.

How far the Government may be prepared to go in aiding such "Homes for Consumptives," need not here be discussed, but it is plain that the disease comes so specially under the list of contagious diseases to be dealt with under the Public Health Act, that local health authorities must of necessity be those who have to take up the practical work in this matter as naturally, and along lines as similar as those dealing with other communicable diseases. When that ponderous body, the London, England, County Council has begun to move positively along the lines of the Royal Commissioners' Report on "Tuberculosis," then may we in Canada with our simpler problems, unhesitatingly deal with and solve them as we have so many other health questions.

So firmly convinced is your committee, that the time has come for an active propaganda for the establishment of County Homes for Consumptives, that it would urge that the Board discuss the plan for arranging for meetings during the coming winter in our principal centres for organizing local committees to act in conjunction with the local health authorities for erecting County Homes in favorable localities.

Regarding the further problem of local cattle inspection and factory inspection, we may expect work in this direction to go hand in hand with that of taking care of those already tuberculized.

With regard to the work of establishing sanatoria elsewhere, we find Chicago has just opened one with a capacity of 350 beds, especially for the consumptive poor; another has been established by the "Sisters of Mercy" in New York State, New York City has a place for its tuberculous poor, at a cost of \$60,000, and Massachusetts has opened one near Boston.

Turning to England, the number of addresses and editorials in the medical journals of the last two months, dealing with this very subject, is most remarkable. That most remarkable is by Sir William Broadbent, M.D., of St. Mary's Hospital, London, at the opening of the Technical College, Huddersfield. After stating that the total deaths in Huddersfield in 1897, from tuberculosis, was one in every 7.5 deaths, he says:—

"It is often the most gifted, the most useful, the most diligent, the most amiable who are carried off in this way." Is this not so? And then it is so tedious and trying and often so painful and distressing a way of leaving the world; and so expensive too, frequently exhausting the entire resources of a family. "Consumption is one of the products of men's ignorance and carelessness."

"The room or rooms in which a consumptive patient has lived and died, ought immediately to be disinfected under the supervision of the medical officer of health.

To prevent the disease in those with inherited susceptibility, he says:—"The most effectual of these is to live as far as possible in fresh air day and night, summer and winter.

Ventilation is of vital importance, "But it is necessary by night as well as day. "I believe that if we all slept with open windows the mortality from consumption would be reduced by one-half from this alone."

"Nothing can be more efficacious in preventing the spread of consumption, than to cure those already affected by it, unless indeed you kill them off out of the way. Now a great deal more can be done to arrest and cure phthisis, than was formerly supposed possible by means of what is called, and what is in truth the open air treatment." We have become alive to the fact that the curative agent is not any particular air, but simply air. Thus the remedy for consumption lies ready to our hands, and instead of being obtainable by only the favored few, is available for all."

Dr. Broadbent referred to a pamphlet by Dr. Philip of Edinburgh, entitled, "On the universal applicability of the Open-air Treatment of Pulmonary Tuberculosis." Dr. Philip at Edinburgh, Dr. Bredon, living on the Norfolk Coast, Dr. Gibson in Ireland, have showed consumption can be cured in practically all parts of our Islands. "If consumption is preventable, it ought to be prevented—if it is curable it ought to be cured. What is needed for this end is, the erection of suitable sanatoria, and these ought to be provided within easy reach of every large town."

"The construction of these sanatoria will be simple. The one thing about them will be that it shall be impossible to close the windows of any room in them day or night. They need be little more than sleeping sheds; but of course they would be made as cheerful and bright as possible. Patients will spend the entire day in the open air, wet or dry, warm or cold.

"Movable shelters will be provided to shield them from cold winds, and to protect them from the rain.

"On no pretext will he sit indoors. The amount and kind of exercise he may take will be determined by his temperature and strength, and his life will be regulated in every respect."

"No great barrack building will be required. A sanatorium will usually consist of a number of small separate pavilions, which will be erected one after the other." Again he says:—

"The Association which I have the honor to represent as chairman of the organizing committee, has for one of its objects, the promotion of the erection of sanatoria in all parts of the country. It is to be hoped, and indeed confidently expected, that local branches will be formed for the purpose of ministering to local needs. Such branches will collect and expend their own funds, and will erect sanatoria at any suitable spot in the neighborhood so that patients will not have far to go away from home. The special function of the National Association, will be to co-ordinate the work of different branches, to stimulate public interest in the prevention of consumption, and to co-operate with all the agencies which have for their object the promotion of public "health."

"Clergymen and ministers of religion, who see in the way of duty so much of the suffering and distress occasioned by consumption will, we think, eagerly grasp the opportunity of informing themselves how the disease may be combatted and prevented, and of disseminating the information among families, reinforcing the efforts of the medical men. School masters and mistresses again can do much to teach the children the lessons of health and self-preservation."

In the *Lancet's* editorial October 29th on Sir William Broadbent's address, it refers to Lord Vernon's efforts to reform public milk supplies, and to the efforts of the Liverpool, Manchester and London Councils, in dealing with the inspection of meat and milk supplies.

The *Lancet* has further an editorial on "Open air treatment of Tuberculosis for Infirmary Patients," by Dr. N. Raw, Medical Superintendent of Mill Road Infirmary,

Liverpool. He has reported "On the need of the establishment of Sanatoria for the treatment of Tuberculosis. After pointing out how the disease is lessened by sanatoria, Dr. Raw gives figures of the records of the Infirmary." He says for whereas in 1893 of the total number of consumptive patients admitted, numbering 349—there were 121 died, while in 1897-98 there were but 195 admissions, and 88 deaths. Dr. Raw explains the principle of the open-air treatment which he says, "can be carried out in this country, thus obviating the necessity of sending tuberculous patients to seek sunshine and air in foreign lands."

He says :—

1. The building should be well arranged with a southern aspect.
2. A dry, pure, well-drained subsoil.
3. Pure atmosphere and abundant sunshine.
4. A large garden or grounds well protected from wind.
5. Sheltered verandahs facing the sun.
6. Proper supervision.

How this idea of small sanatoria of simplest characters has spread, we see in Dr. LeGendrie of Paris, pleading for a number of small sanatoria, in order to obtain the best results.

Reverting to the problem of what must be dealt with in the class of institutions we have been referring to, the test of occupations given already, and the percentage of those of the working classes, sufficiently answer the problem.

As Dr. Knopf of New York, in a late paper on the "State and Municipal care of Consumptives, says in answer to this question, any government (State or Municipal) must, if it is earnest in its endeavors to control tuberculosis effectually, take upon itself the care and treatment of all curable and incurable cases of tuberculous patients, among the poor and those of limited means. I mean here by limited means, a practical condition which does not permit a tuberculous patient to enter a private sanatorium or to have at home such medical hygiene and dietetic care as will assure him the best possible claim for recovery."

To determine who such are, there should, Mr. Knopf says, be special official medical enquiries to determine—

1. By medical examination, the condition of patients.
2. To institute hygienic measures in his home.
3. To examine other members of the family for initial tuberculosis.
4. To report condition of dwelling to sanitary authorities.
5. To determine the financial state of patient and his family.
6. That where necessary the state may care for patient.

Smallpox.—The past quarter has, as previous ones during the year, been marked by a low mortality from the several contagious diseases. It has, however, been marked by the appearance of smallpox in three municipalities; a convalescent case having escaped from Detroit to Chatham, another person resident in Camden Township (Kent Co.) having brought the disease from Detroit, while a third case came to Cobourg from Rochester. Owing, however, to the measures taken by the local authorities, supplemented by the action of your secretary, there was no extension from the first houses infected in any case. The cases have been :

Chatham	1
Camden	4
Cobourg	1

With the disease present, however, in a number of municipalities in New York State, many cases in Ohio, and cases occurring at times in Michigan, it will be seen that we are likely to have occasional cases introduced into the Province during the winter, and local authorities are advised of the danger from the general neglect to vaccinate school children. With the preparation of glycerinated vaccine now becoming so general, and the use of antiseptic methods in its preparation, there ought to be no hesitation in having this certain preventative against smallpox generally carried out.

The monthly deaths from diseases reported by all Division Registrars show very concisely the actual condition of the public health as regards contagious disease. Your secretary is especially gratified, as Deputy Registrar General, in being able to report that these reports were received from 707 out of 750 municipalities for October, being a report on 97 per cent. of the total population of the Province. This work has steadily gone on, and if the work of the Local Boards were on a par with the assiduity of their secretaries, the present rate of deaths would be still further reduced.

Scarlatina has notably increased in prevalence, the chief centre being, as last year, Toronto. Until actual medical supervision, as is provided in New York, Boston and other places, made by morning visits of medical men to the schools,—and thereafter carefully following up to their homes absentees, and those who may have been exposed in a room where scarlatina, diphtheria, or measles may have been,—it does not seem that any other means will serve to deal effectively with these diseases. To illustrate this point we need only take the results of a year's medical inspection of the schools in Boston, Mass.

	Total Deaths.		
	1894.	1895.	1896.
Diphtheria	817	588	516
Scarlatina	192	114	121

Scarlatina being often mild, no physician is called on, often for fear on the part of the parents that their other children will be isolated and the house placarded. Learning from the schools of absentees would enable the health authorities to ferret out such cases and have them isolated.

Typhoid fever has been more prevalent, as usual, during the past quarter than during any previous quarter of the year. How your Board is going to deal with this prevalence, which is almost wholly in rural districts and villages, where well water is wholly used, is a problem demanding solution. Wells tell still the old story; and the remarkable fact exists, as will be shown in a supplementary report by the bacteriologist of the Board, on an outbreak in one of the oldest and wealthiest townships, that the farm wells of to-day seem to be located with as little regard to health as fifteen years ago, and are subject to pollution in the same way. There seems no present solution, except the radical one of a County Health Officer with plenary powers to institute systematic investigations, and have new wells constructed and located away from the local sources of pollution.

The local nuisance problem in the rural districts and smaller towns equally demands urgent consideration. Such a condition as that illustrated by the report forwarded to this Board by the Department of Agriculture at Ottawa regarding the condition of large piggeries near Ottawa, where the city offal is fed, reveals a state of affairs which your Secretary has again and again vainly attempted to have dealt with by the Local Board of Health. Conditions but little better exist in the neighborhood of all our larger centres, and in spite of the fullest powers to deal with such under the Act, the rural boards have proved utterly useless for the purpose. Raw, putrid offal is systematically fed, although the animals are liable to seizure and a heavy fine for the offence can be levied. Again the county officer with full powers to inspect, suggest remedies, and prosecute for non-compliance is so far as I know the only remedy.

Complaints having been made of the pollution of the Welland Canal waters, which flow from Lake Erie, by the drainage from large swamps in Humberstone and Wainfleet Townships, your secretary visited the district. Welland, Merriton, and St. Catharines all use the canal water as a public supply, and it is essential that such be maintained pure. A full report on the effect of the several pollutions will be made when the investigations are completed.

Several outbreaks of diphtheria have occurred in the back settlements and unorganized districts of Frontenac, Hastings, Muskoka and Parry Sound, which will be found referred to in the correspondence.

REPORT ON TUBERCULOSIS IN ITS RELATION TO MILK PRODUCTS, AND ON INSURANCE SOCIETIES AND CONSUMPTIVE SANATORIA.

Quarterly Report of the Committee on Epidemics.

TORONTO, 31st January, 1899.

Mr. Chairman and Members of the Provincial Board of Health :—

GENTLEMEN,—The past quarter has not been marked by any special prevalence of contagious diseases in the Province, dealt with under Public Health Act, although the remarkable climatic changes of the past month, have been productive of an abnormal prevalence of diseases of the respiratory tract, and notably of Influenza, showing in many instances a markedly infectious character.

Such influences have similarly tended to an increase in diphtheria, of which the monthly reports show 51 deaths or a rate above the average for the year.

Typhoid fever has shown a notable decrease in deaths, there having been in December, only 21 deaths. Reports from Kaladar Township have come to hand, telling of a notable prevalence of the disease for several months past, in the rural district amongst poor settlers, and points to the obvious need of some means of systematic investigation and control superior to that possible in a township with a population of 360 ratepayers, and an assessment of \$73,000 with a tax of 19 mills. Such outbreaks illustrate the absolute necessity for a trained County officer, who could devote the necessary time to the control of such an outbreak.

Scarlatina shows a low incidence during the quarter.

Smallpox is however again present in the Province, while its prevalence in surrounding States, with its appearance in immigrants from a European port, and its presence in Quebec, Manitoba, and British Columbia, all call for the prompt action of the Local Boards of the Province in preparing for its approach by at once taking steps for a general vaccination of our people, who have greatly neglected this precaution since the great Montreal epidemic in 1885.

The statement as seen in the table submitted shows the actual status of the disease in all neighboring states and in the Province.

The scientific progress in the last few years in the preparation of aseptic glycerinated calf-vaccine lymph has made great strides. The Local Government Board of England, has instructed public vaccinators to use glycerinated calf-lymph in preference to humanized lymph.

Health authorities of New York, Chicago, and other places, are preparing and using it; large private firms have it on the market, and your Committee would advise that the proprietor of the Ontario Vaccine Farm, be notified to arrange for the preparation of lymph in a similar manner.

The splendid results of such glycerinated preparations, in successful vaccinations and the absence of suppuration, when the operation is carefully performed, encourage the hope that any apprehension on the part of any person as to the results of vaccination, may be wholly removed. What the unvaccinated are exposed to, is seen in the unfortunate case of the young man in Walford Township, who died on Saturday last. The medical health officer reports the receipt by deceased of a letter from a brother in British Columbia, and written apparently from a house, wherein, as the letter states, "his employer had just died of smallpox." No other sort of contagion seems possible, so far as reports go. Owing to the delay of six days before the nature of the disease was discovered, others of the family are likely to take the disease; neighbors exposed, and there is almost a certainty of a number of more cases occurring. With prompt action by the

local authorities, there is reason to hope that the outbreak will be limited. There will, however, be a serious expense to the municipality involved; yet if municipal authorities and private persons continue to neglect vaccination, such expense may be expected.

Owing to cases reported in Hawkesbury East Tp., Prescott Co., contiguous to the Quebec County of Soulanges, where several cases exist, a Medical Inspector of your Board has been dispatched, to visit the districts where cases are reported, and to take steps to have the local authorities active in the suppression of the outbreak. What further steps may be deemed necessary to be taken in view of the present situation, will be for your Board to determine.

Tuberculosis.—The past year has been marked by remarkable activity in different countries as well as in the Province, in the progress of the movement for suppressing the prevalence of tuberculosis.

This has taken two directions, the one, the establishment of Sanatoria, for treatment and of notification of cases; and the second has been the renewal of the crusade against milk and its products, which may carry the germs of tuberculosis.

English public opinion so conservative, so slow to be aroused to action, yet so characteristically practical when aroused, has, during the past year, years after France, Germany and Denmark have instituted practical measures for dealing with the disease, developed an activity positively surprising. By far the most advanced in its systematic municipal sanitation, which in England has in 30 years caused the mortality from consumption to be reduced 50 %, and has resulted in a death rate in that densely populated country of but 1.3 in the 1,000 or lower in 1896, than Ontario in 1897, the English people, led by His Royal Highness, have declared that tuberculosis is a disease which can be prevented, and therefore must be, and a National Association with him at its head, has been formed to aid municipal establishment of local sanatoria for its treatment. But more than this, they have by a Royal Commission based on experimental evidence, declared that the dairy is a fruitful source of this disease; and experimenters are there daily accumulating further evidence of its truth.

The most recent of such results are those published in the *Lancet* of January 14th, 1899, giving the experiments instituted by Prof. H. H. Kanthack, Professor of Pathology, Cambridge University, and who has died almost on the completion of the work.

The investigation was begun in April, 1898, as to the effects of the milk supply sent daily to the different colleges of that city. Daily samples were taken direct from the milk cans of vendors, and from a half to a drachm of the creamy portion, and of the sediment were injected into the groin of guinea-pigs, each into a separate animal. Microscopic examinations were also made of each sample.

Summed up, the following results were obtained: Of the ninety guinea-pigs inoculated, twenty-three died, or 25.05 per cent. Of these, thirteen were from the creamy layer, and ten from the sediment.

Of the sixteen dairies examined, all supplying mixed milk, nine supplied milk which caused tuberculosis. The report states: "It is therefore not unreasonable to regard these dairies as a grave source of danger."

The same number of the *Lancet*, in its Berlin correspondence, gives the latest results of experiments at the Imperial Hygienic Institute, on tubercle bacilli in butter. Dr. Obermuller found bacilli in each of fourteen samples supplied by the same tradesman. Dr. Hermann found it in fifty per cent. of ten samples from three shops. Dr. Petre, of the Imperial Health Office, found them in 32.3 per cent of ten. samples from different shops.

Dr. Lydia Rabinowitch found in one set of samples seventy per cent., and in another set from the same shop one hundred per cent. containing bacilli. All the animals inoculated with this butter produced typical symptoms of tuberculosis.

It was remarked that the most numerous and virulent samples were from the principal shops in Berlin.

Remembering the long repeated and strenuous endeavors of this Board to point out to the public, and to local health authorities, the danger from infected milk products, remembering that the actual deaths in Ontario from diseases returned as tuberculosis have reached in 1897 for the first time 3,000, or 3,154 exactly ; remembering that in the class returned as infantile debility, atrophy and premature births of children under one year, many, and probably most of which were tubercular, there were 2,279 deaths, 1,709 congenital debility, 574 other diseases of infancy ; remembering that this class of diseases in England has not decreased notably, while consumption proper is lower than in Ontario ; it seems regrettable in the extreme, that after all efforts put forth, but two, or at the most three, of our 747 municipalities have attempted to deal with the question of milk from tubercular cows. And is it to be wondered at, when we see one of the leading dailies, which wields so potent an influence upon public opinion, publishing twice within the past few months, articles on the "Tuberculosis Scare," making statements showing apparently a marvellous ignorance of facts, which have been abundantly illustrated in a hundred laboratories, and by the tell-tale statistics of the registration returns of every country and large city in the world ?

We have seen years of neglect of cattle inspection result in the embargo being placed on Canadian cattle in England ; we have seen, to remedy the exclusion of American bacon from Germany, an elaborate Governmental system of inspection in the United States of hogs for export, and now we see added to this a close inspection of all dead meat for export from that country, establishing for them a reputation Canada will not readily establish, if she does not follow with similar work.

Now, we hold largely the cheese market of Britain, and hope to gain the butter market. But if we are to maintain our present position, if we are to gain what we are longing to obtain, surely those who are seemingly prepared to close their eyes to what affects the lives of our own people, will begin to see that the interests of true commercial enterprise demand that we send commercial products to foreign countries with such an assured wholesomeness that there will be no danger of our losing what it has taken such great pains to obtain.

In the report of Dr. McEachren published in August, 1898, by authority of the Minister of Agriculture, Ottawa, the magnificent commercial results of the scientific production of milk in Berlin, and of the Milk Supply Company of Copenhagen, are illustrated, and if it were necessary the results of similar methods in use on this continent could be quoted to amply indicate that any attempt at reactionary methods, whether private, municipal or governmental in this work, based upon science, must to-day end disastrously and in commercial loss.

That these views will be borne out in practice may indeed be further argued from what has appeared in the to day's telegraphic despatches from Britain in which the committee of the British Medical Association appointed to consider the tuberculosis question is reported as stating that municipal authority should be exercised, 1st to prevent any house from being built unless it be on a dry site and foundation, with sufficient space to admit free sunlight and air ; 2nd that such authorities should be empowered and required to construct municipal abattoirs and that killing of meat be prevented elsewhere ; and 3rd that inspection of cowsheds and cows should be regularly carried out and that all milk for public use should be prohibited, where the tuberculin test had not been applied.

Sanatoria for Consumptives.—The agitation for the erection of sanatoria has developed with amazing rapidity. Although such have existed for years it is but very recently that their development has become systematized. As in so many other scientific phases of Medicine, Germany has led the van in this work, and it has been curiously illustrative of the intimate relationship which the financial aspect has with sanitary development.

As early as 1867, Dr. Schæffle began the agitation there through his writings for compulsory workmen's insurance. The Hon. Joseph Chamberlain in England has agitated for it, and claims that though such insurance be socialistic, it is less harmful as Schæffle asserts, than are existing forms of charity.

When the bill re compulsory workingmen's insurance was being debated in Germany in 1881, Bismarck said, "Call it socialism or whatever you like, it is the same to me." Up to this time, great development of insurance through friendly societies had taken place, but in 1883, compulsory insurance for sickness and accidents became a part of Imperial Legislation. The bill was intended to apply as early as practicable to 12,000,000 people. Under the bill all laborers, artisans, post and telegraph operators, soldiers and sailors and others whose daily wage does not exceed $6\frac{3}{4}$ marks (or \$1.59) were included. There are commercial, local and state insurance organizations, as well as those of different classes of artisan or guild and free associations or friendly societies. The largest are the commercial, probably over 40 per cent. belong to these.

Every man obliged to insure belongs to that local factory, guild, or other association which exists where he works.

The contributions are based upon the rate of wages, it may be up to 2 per cent. of their wages. The expenses of any association must in no instance be more than $4\frac{1}{2}$ per cent. of the wages.

The aid given varies in different associations to different classes of persons.

The minimum sick pay is 50 per cent. of the average wage, and the limit of its payment is usually up to thirteen weeks, but may continue for a year. Instead of medical attendance and sick pay, free treatment in an hospital may be given. In the case of death twenty times the amount of wages of common laborers is given, and in no case more than forty times the amount of this sum.

In 1891 the cost of sickness in the dif-

ferent associations amounted to..	\$21,312,610 00	= 90.61 per cent.
Cost of administration.....	1,175,968 00	= 6.02 "
Expense for number insured in 1891	3.58	"
Total associations in 1891	21,498.	
Cost of medical attendance and medicine, 1891.....	\$7,399,125.	

These figures have been given in semi-detail in order that the scope of these associations may be understood and that their relation to the growth of the sanatoria for Consumptives may be seen.

Since the institution at Gorbersdorf, in 1862, of Brehmer's Sanatorium, and of Detweiler's at Falkenstein a few years later, it has gradually come to be understood that consumption dealt with promptly and intelligently is in large measure a curable disease. In one report which has come to hand of the operations of Dr. Weicker's Sanatorium at Gorbersdorf, for 1897, where there are now several of these institutions, it appears that 547 were treated in 1896 of whom 62 only were supplied wholly by the insurance companies. Of the other 485 cases the daily cost was 3.96 marks, of which 121 m. was private funds and the balance 2.75 m. supplied by the insurance companies were sent there by some of these insurance societies. The term there for which they received the sick benefits was 13 weeks. At 50 per cent. of the wage \$1.59, they would be paid \$5.60 a week, so that it will be seen that an ample amount was paid, if it all went to the sanatorium for their care. The remarkable fact is stated in the report that of the workmen thus sent away, 80 per cent. were reported so cured in 13 weeks treatment as to resume work, the workpeople doing better than the others comparatively. One reason being given, viz, that they were sent early. Many interesting details might be given from this report but the chief one is that of the fresh-air treatment and strict sanitary regimen, with easy tasks interspersed with recreation.

To what an extent these sanatoria are being utilized by the insurance societies in Germany, from the purely commercial standpoint, that of saving money in death claims, may be gathered from the fact that in 1898, they have paid between three and four million marks for the maintenance and erection of such sanatoria for the people or nearly a million dollars. As stated in a recent number of the *Lancet*, elaborate statistics are given by one institution of 1,541 phthisical patients, showing that general improvement has taken place in 85.5 per cent., local improvement in 61.1 per cent., complete restora-

tion of working capacity in 71.8 per cent. In 15.5 local signs, slight on admission disappeared, 15.4 local signs remained unchanged, and in only 6.6 per cent. did local signs increase. It is also shown that a large proportion of those treated in former years remained well. These statistics are given of sanatoria, not in mountain regions only but in the best selected sites in various localities.

We are thus brought again to the subject of dealing with such in our own Province. In the five years' statistics of deaths in Toronto, ending 1898, it was shown that some 80 per cent. belonged to the artisan classes most of whom are in positions comparable to those treated in Germany, and whose deaths leave so many families dependent on charity. How shall the matter best be taken up in our Province? At present we have no compulsory insurance law, but we have hundreds of friendly societies. Surely the local health authorities may be expected to aid in the establishment of institutions, where these societies may be expected from the purely financial standpoint, apart from that of brotherhood, to supply the funds for the care of their sick, while others would be similarly maintained by friends and the church organizations to which they belong.

QUARTERLY LABORATORY REPORT.

By J. J. Mackenzie, B.A.

Toronto, May 19th, 1898.

The Chairman and Members of the Provincial Board of Health:

GENTLEMEN,—In connection with the work in the laboratory of the Board, I beg to present a report of the work done in the five months ending April 15th. I select that period, as it includes the winter months, and will show the extent to which the work has increased.

In presenting this report, I wish to especially call attention to the necessity of the Board taking some steps to either lessen the amount of routine work, or to provide means to overtake it, as matters have now reached such a point that I find myself unable to overtake all that is sent in, and I cannot find time for the more important scientific investigations which are continually presenting themselves, and which would be of special interest to the Board, if carried out in its laboratory.

I have endeavored, also, as showing the methods pursued elsewhere, to collect data as to the laboratory work done by other Provincial and State Boards of Health.

During the past five months, there have been examined in the laboratory, 581 samples of suspected diphtheria; 58 samples of suspected tuberculous sputum; 31 samples of suspected typhoid blood; 74 samples of water, and 44 miscellaneous examinations. This is an average per month of—

Diphtheria swabs	116
Water samples	15
Sputum	16
Typhoid	6
Miscellaneous	8
Total	155

In addition to this, I have (excepting the serum for the diphtheria examinations) to make up all my own media and prepare all the other material used in the laboratory, and also carry on the clerical work of reporting results. That the work will continue to increase is to be expected, and this increase will become more rapid as the districts availing themselves of the laboratory, become more numerous. The effect of this press of work has been that reports are delayed; that sufficient time cannot be given to the work, and that special investigations are absolutely stopped.

I began over a year ago an investigation upon rabies, which I have been compelled reluctantly to give up in spite of the fact that I have succeeded in accumulating a lot of valuable material, if only time could be obtained to work at it.

The question of antitoxin tests is of pressing importance, but so far only one sample has been tested, a report of which was presented at the last meeting of the Board.

The question of formaldehyde disinfection, and the most practical methods to be used under the conditions obtainable in Ontario, is another subject which should have been taken up before this.

In the matter of bacteriological water analysis, I feel particularly the need of time. Every sample of water requires to be studied specially from a bacteriological standpoint, and may be considered in each case the subject of a special investigation, but at present we must content ourselves with a quantitative examination, and a very cursory qualitative examination, with the result that it is difficult sometimes to give a safe opinion upon the water. A point of more than ordinary interest, is the bacteriology of our northern Ontario brown waters, and the behaviour of pathogenic bacteria in them, and until the question is thoroughly studied, we may say we have a quantity of unknown conditions present of a hygienic character, which render difficult the questions of pollution and potability of these waters.

There are two possible solutions in this question, one is to put a certain restraint on the work by charging a small fee which would be applied to meeting the expense of the laboratory; the other is by giving the assistance necessary to carry on the work.

The first method is the one pursued in a good many States, but it would be difficult to retire from the position which we have taken, of doing the work gratis.

The second method must be resorted to sooner or later, even if fees are charged.

I have prepared a short statement of the methods pursued elsewhere, which is as follows:

In Quebec there is a chemist and bacteriologist employed by the Board, who are paid a retaining fee, and receive the fees for the work done. They each depend for assistance chiefly upon that which they receive from their University or hospital positions.

Fees charged are as follows:—

Water—Chemical	\$15 00
“ Biological	15 00
“ Combined	25 00
Milk—Chemical	5 00
Sputum	5 00
Meat	5 00
Special	\$10 00 to 20 00

In Michigan the large staff of the State University is used, and fees are charged for the work done.

In Pennsylvania there are two chemists and two bacteriologists, besides assistants. These officials hold other positions, but devote a certain time to State work. The State charges fees as follows for each sample of water, chemical or bacteriological, \$7.50.

For private diphtheria examinations, \$1.50. Every municipality can, however arrange for diphtheria examinations by paying according to population, as follows:

5,000	\$ 15 00 per annum.
10,000	25 00 “
15,000	30 00 “
20,000	35 00 “
25,000	40 00 “
30,000	45 00 “
50,000	50 00 “
Over 50,000	100 00 “

In Massachusetts no fee is charged, and the state maintains a staff of sixteen to do chemical and bacteriological work, with the result that the Massachusetts State Board of Health are everywhere considered the most valuable sanitary publications in the world.

In New Jersey there is no chemical work done by the board, the bacteriological work is done free of charge by a chief bacteriologist and assistants.

In New York chemical analyses of water are done by the board. The bacteriological work of the board is done outside and fees are paid.

In Wisconsin a State chemist with assistants does the chemical work. There is a consulting bacteriologist paid by and the secretary of the board does diphtheria and sputum free of charge.

In Indiana the work is done free of charge to municipalities, but is paid for by the State, the State board reserving the right to refuse to do work if appropriation is expended.

In Ohio the State chemist does the analytical work free of charge, and they are now endeavoring to obtain the appointment of a bacteriologist.

In Minnesota the work is done free of charge; there is a State bacteriologist who does no chemical work and who has three assistants.

It will be seen from this brief synopsis that in some States fees are charged, in others none; but in all cases it will be noted that a much larger staff is required to do the work in practically every instance where the chemical work is separated from the bacteriological.

What is required here is that the chemical work should be separated. Not only does it break into the ordinary bacteriological work, but also no chemical analysis to be accurate should be made in a bacteriological laboratory. There is required also an assistant, who would be able to do a certain amount of the routine work of making media, making diphtheria and sputum preparation for examination (under control of course), and reporting of results.

If this were done, the value of the laboratory to the Board would be enormously increased, and work could be carried out of much more lasting benefit to sanitary science than the mere routine examination of swabs and sputum.

OUTBREAK OF TYPHOID FEVER IN HAMILTON TOWNSHIP, DURHAM COUNTY.

By J. J. Mackenzie, B.A.

Toronto, Nov. 29th, 1898.

To the Secretary, Provincial Board of Health :

DEAR SIR,—I beg to submit a preliminary report upon an outbreak of typhoid in the Townships of Hamilton and Hope which I have been investigating.

The outbreak has been chiefly in the Township of Hamilton and is confined to nine houses within a comparatively limited area set forth in diagram; in all there were twenty-one cases with one death.

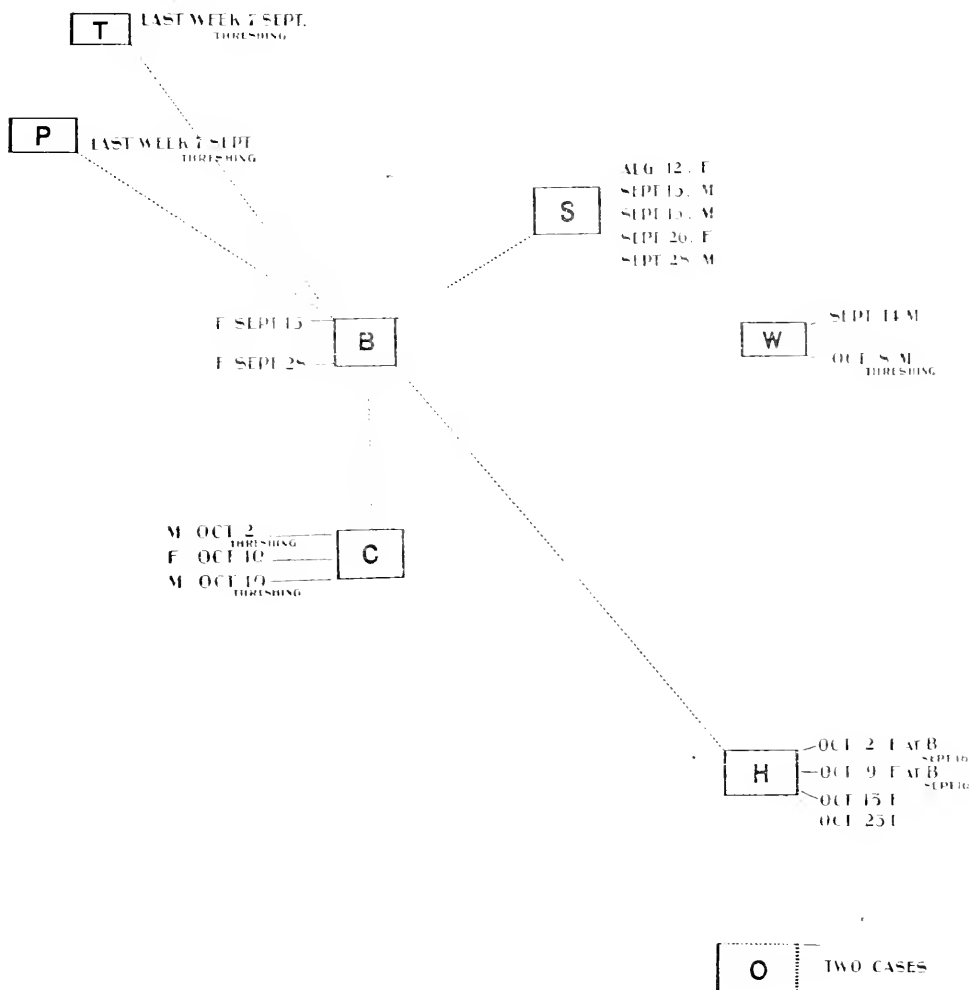

The outbreak began with a case in the S—— household on Aug. 12. In regard to this first case, I could not find any history of exposure to infection. The patient had been in Port Hope for a few hours on one or two occasions but had been chiefly at home.

The next case developed in the same household on Sept. 13, a third on Sept. 15 and two more before the end of the month.

On Sept. 15 a case developed in the B—— house, situated a few hundred yards from the first house and in a family using water from the S—— well.

On Sept. 12th there was a threshing bee at the B—— house and the water used came from the S—— well, and of twelve who were present six took typhoid. It would look as if this threshing were the opportunity for infection and the cause of infection the water of the S—— well which was used by the threshers. Unfortunately for this

DIAGRAM SHOWING POSITION OF HOUSES WHEREIN OCCURRED
CASES OF TYPHOID FEVER IN HAMILTON TOWNSHIP.

theory, however, the cases developed somewhat late. Taking all the 21 cases by weeks the incidence was as follows :

Week ending Aug. 13.....	1 case.	(S—.)
“ Aug. 20.....	None.	
“ Aug. 27.....	None.	
“ Sept. 3.....	None.	
“ Sept. 10.....	None.	
“ Sept. 17.....	4 cases.	{ S— 2. W— 1. B— 1.
“ Sept. 24.....	2 cases.	{ T— 1. P— 1.
“ Oct. 1.....	3 cases.	{ S— 3. B— 1.
“ Oct. 8.....	4 cases.	{ C— 1. H— 1. W— 1.
“ Oct. 15.....	3 cases.	{ H— 1. H— 2.
“ Oct. 22.....	1 case.	{ C— 1.
“ Oct. 29.....	1 case.	{ C— 1. H— 1.

Finally two cases which I have no date for as yet.

Of the cases which might be traced to drinking water at the threshing two developed within two weeks, one three weeks, one three weeks and six days and one five weeks and three days.

There were four cases in the H— household, all females. The first two had been at the B— house about Sept. 16th, and probably drank the water there; they developed typhoid two weeks and three weeks later. Two others developed in the same household, one Oct. 13th and the other Oct. 23rd.

There is finally a case, W—, who developed the disease on Sept. 14th and who was not at the threshing. This case was a boy and the father was at the threshing and developed but not for three weeks and six days after.

It was difficult to obtain exact facts as to the extent to which these cases visited either of the infected houses, but I think it is probable that there was more exposure than is indicated.

In regard to the general features of the outbreak it is to be noted that the first case preceded the others by over a month. It also preceded the other cases in the same household by the same period, and beginning with Sept. 12th and taking the period until Sept 30th, of nine cases which developed, six are known to have used the S— well constantly, whilst two used at the threshing. One only remains in doubt as to the infection.

It seems probable, therefore, that the water of the S— well became infected between Aug. 12th and Sept. 12th, and that a fair proportion of the cases were due to the use of this infected water.

The well is situated in the yard near the kitchen, it is about 30 feet deep through clay and has a good supply. Is not known to go dry. Fifty-seven feet away is the privy box, a dry earth affair, which is however only cleaned spring and fall. About the same distance is the stable and ground around the well is in a very filthy condition.

An analysis has not yet been made of the water, but I have no doubt it will turn out to be bad.

The meteorological conditions do not seem to throw much light on the cause of the outbreak except that the weather was exceptionally hot during the first four days of September and there was rain at Port Hope on the 4th, 5th and 6th.

It is probable that a certain number of cases which occurred after Oct. 9th was due to direct infection from previous cases in the same household, as in all cases there were cases already in these houses.

The cases according to families were as follows :

S— family.....	5	H— family.....	4	T— family.....	1
B— “	2	W— “	2	P— “	1
C— “	3	A— “	1	O— “	2

THE DISINFECTION OF THE DOMICILES OF TUBERCULAR PATIENTS.

November 30th, 1898.

By J. J. Cassidy, M.D.

To the Chairman and Members of the Provincial Board of Health :

GENTLEMEN,—The necessity of disinfecting the domiciles of persons who die of tuberculosis, or even rooms in houses which have been temporarily occupied by tubercular patients seems obvious enough to sanitary authorities. And the reason for that is simply because we believe that tuberculosis is a disease which may be transmitted from one person to another. Remove the cause and the effect disappears. In fact, one of the postulates of sanitary science in reference to the prevention of tuberculosis is : Remove the bacilli tuberculosis from inhabited places, prevent the deposition of fresh bacilli therein and a vast diminution in cases of tuberculosis will soon be apparent. This doctrine has not yet received the adhesion of all physicians, some of whom are incredulous of the transmission theory and believe that tuberculosis is caused by a degeneration of the organism resulting from hereditary weakness, overwork or excesses, together with insufficient or improper nourishment. Needless to say, a layman who derives his views and the etiology of the disease in question from such a professional source will not notify the municipal health department that a tubercular son or daughter has occupied a room or rooms in his house. Neither will a hotel-keeper inform the health department that a tubercular guest, who has gone south for the winter or become an inmate of a sanatorium in Ontario, occupied a room in his house for several months. To overcome this obstacle I would recommend that tuberculosis be made a notifiable disease, the subsequent management of any given case to be conducted so as to obtain the best result whether in a domicile or at a sanatorium. Owing to the wide prevalence of tuberculosis in Ontario, there being an annual mortality from that disease of 2,757 in 1896, it is most important that notification should be given to the civic health authorities, because no matter what the termination the case might be, the disinfectors could take suitable means in the infected locality to destroy the bacilli which are the active agents in propagating the disease.

In order to ascertain the practice among Ontario health officers in this matter a circular letter, asking if disinfection of the domiciles of tubercular cases is done by the civic health department and in what manner, was sent by me to the medical health officers of Toronto, Hamilton, London and Kingston. The following replies have been received :—

TORONTO, November 25th, 1898.

DR. CASSIDY,
69 Bloor St., East, City.

DEAR DOCTOR CASSIDY—In reply to your communication of November 23rd, I desire to state that in a number of cases disinfection of the domicile after tuberculosis patients have died or vacated the premises is asked for and done by the department, in which cases the rooms are disinfected with 1 to 1000 of bichloride, and the bedding, etc., by steam sterilizer.

Faithfully yours,

CHARLES SHEARD, M.D.,

Medical Health Officer.

HAMILTON, ONT., November 28th, 1898.

DEAR DR.—No disinfection has been applied for after the death or removal of a tubercular patient in this city.

Yours respectfully,

L. RYALL,
Medical Health Officer.

J. J. CASSIDY, Esq., M.D.,
Member Provincial Board of Health,
Toronto.

LONDON, ONT., November 29th, 1898.

MY DEAR DOCTOR—Concerning tuberculosis. Disinfection after death from tuberculosis or removal of patient of house, dwelling or home has been asked for only three times during the year in this city. Formaldehyde was the agent used. I am doing my utmost to educate the people up to the necessity of disinfecting, isolating and in every way circumscribing the direful ravages of this disease.

Yours very truly,

T. G. HUTCHINSON,
Medical Health Officer.

J. J. CASSIDY, Esq., M.D.

KINGSTON, ONT., November 28th, 1898.

DEAR DOCTOR—In reply to your enquiry. My answer is, no.

Your obedient servant,

SAMUEL H. FEE,
Medical Health Officer.

BROCKVILLE, ONT.

Dr. Vaux had one case in which application for disinfection was asked for after death of a patient.

It is quite evident from these replies, that this most important feature in the prevention of tuberculosis is neglected in Ontario. As illustrative of what might be done to decrease the prevalence of tuberculosis in this country, I shall read you an abstract which I have made of the Parisian method of disinfecting the domiciles of the tubercular poor. At the congress of tuberculosis, held at Paris, last July, Dr. [A. J. Martin, Inspector General of the health department of that city, read a paper, descriptive of the efforts made to restrict human tuberculosis by procuring the disinfection of the lodgings, occupied by tubercular patients. He endorsed the recommendation of the French Academy of Medicine, which favoured (1) the use of spittoons for the pocket or the apartment; (2) the disuse of sweeping and the use of a damp mop for cleansing floors; (3) disinfection of the domicile after a patient's death, or even after a short occupation of the premises by a tubercular patient, and also disinfection of the body linen, bed linen, etc. After describing the present status of gaseous disinfection by sulphur or formaldehyde, Dr. Martin gives the preference to the washing or spraying of surfaces with antiseptic liquids. Washing or spraying, the latter especially, if done in a careful manner by practised hands, possess the double advantage of securing the cleanliness of

the place to be disinfected, and rendering it habitable in a relatively short period. The necessary displacement of the furniture, also brings into notice portions of the room, which, too frequently remain in a flagrant condition of filth. Floors are scrubbed or mopped. Whitewashed walls and ceilings are retouched. Where the walls are papered, antiseptic sprays of mercuric chloride and chloride of sodium are used, and a sterilizing of tubercular dust has been thus obtained, equal to what has resulted from a lengthy contact of the surfaces of a room with an antiseptic gas. The principal antiseptics used are:—Fresh milk of lime; solution of chloride of lime; (100 grains of commercial chloride of lime to 1,200 grains of water, then, after filtration, dilute to a strength of 1 in 10; solution of commercial formol, 5 grains to the liter of water; solution of carbolic acid, 5 per cent.; solution of cresyl, 5 per cent.; wood vinegar; solutions of soap, and especially the solution of mercuric chloride mixed with chloride of sodium, which, as Miquel has recently shown procures the definite and immediate sterilizing of tubercular sputa, owing to the property possessed by the chloride of sodium of dissolving the insoluble albuminate of mercury.

The disinfection of domiciles for tuberculosis has now been in operation in Paris for six years. The number of disinfectants asked for or accepted, was 4,541 in 1892; 8,128 in 1893; 7,514 in 1894; 9,225 in 1895; 9,330 in 1896; 10,194 in 1897 and 6,979 in the first half of 1898. These figures will be increased during the second half of the present year, because the sanitary authorities of Paris intend to extend, experimentally, to an entire arrondissement of the city the preventive measures, which have been applied systematically to the tubercular poor, who have been cared for in their own homes. Over two years ago the French Commission on tuberculosis had recommended a certain number of preventive measures to be put in force in the case of poor people treated in their own homes. Closely adhering to the instructions of the commission the following plan of action was adopted: (1) Two spittoons were placed in the domicile of each patient. After different trials, the department decided in favor of a colored glass article, flat-bottomed and formed of two opposite cones, it is made so that, the fingers are protected against soiling by the expectoration, which drops easily into the contained liquid and it is steady enough to be placed near the patient, who, in many cases, is often left alone in his room. It seems to answer better than the heavier articles, formerly in use, for which the patients substituted a wash-basin or enamelled spittoons. (2) A certain amount of liquid should be left in the spittoon. This regulation has been generally observed, but, in a good many cases, the patients have objected to carbolic acid on account of its disagreeable odour increasing their cough. Then water is therefore used instead. (3) The spittoon should be cleaned every day, by putting it into cold water, which is subsequently raised to the boiling point. The physicians, however, unanimously recommend, that the spittoons should be emptied into the water closets and then rinsed out. The department agree to this innovation, being convinced that in the houses of the poor, it is often impossible to obtain the cleansing of a spittoon with boiling water, as frequently the necessary kitchen utensils are lacking and for the greater part of the year a fire is not available. (4). Soiled linen ought to be steeped in boiling water for five minutes. For reasons similar to those last given, in nine-tenths of the cases, this precaution could not be observed. Where conveniences were wanting, the department recommend that the soiled articles be put aside, so that they could be disinfected by the municipal sanitary service. This was done and without much trouble, save in one of the quarters of Paris, where the tubercular poor had no linen to wash. The public assistance will assuredly interfere to provide for such a lack of clothing. (5) After death, cure or departure, the disinfecting service perform the usual offices without much difficulty. The disinfectors go at least once a week to the domicile of each patient. They exchange disinfected linen for the soiled linen, which they carry off to the disinfecting machine; the water closets and utensils, used by the patients, are cleansed with antiseptic fluids.

The greatest obstacle to practical disinfection has been the notification of the patient's disease to the authorities. Soon after notification the patient was considered, as if he were a leper and, in some instances, was expelled from his lodgings. Thus the disinfecting operations were not regularly and completely carried out, except in a little over 50 per cent. of the cases. It was the same after a death. These difficulties, however, were

noticed only in some places. The spittoons and disinfection were accepted and even asked for in three arrondissements, in two other arrondissements, however, some ignorant or evil-minded neighbors caused the failure of the municipal preventive measures. "The spittoon is a great success, says one of the physicians, who have taken most interest in introducing it, because it collects all the contagious droppings, which, formerly, were discharged at the caprice of the patients, and most frequently on the floor of his room. Our tubercular cases accept freely the spittoons and the weekly cleansing of the water-closets. The sanitary service does the work with regularity."

The regular disinfection of consulting rooms, houses of refuge, civic offices or places frequented by the tubercular poor is done without difficulty. Whenever a tubercular patient is admitted into a hospital, notification by telephone is sent to the civic health authorities, who immediately despatch the disinfectors to do the necessary work at his vacated domicile. These officials are not in all cases permitted to do this office, for the simple reason, that the transmission of tuberculosis from one person to another is still very far from being believed in by the Parisian people.

Such are the measures which will be systematically applied, as fully as possible, in one of the arrondissements of Paris, and, doubtless, later on in others. Joined to disinfection directly asked for or accepted after a death has occurred or during the course of a patient's illness, as well as disinfection of lodging, after location and before inhabitation, which is asked for more and more every day, the sanitary resources of the French capital against tuberculosis will be very much strengthened and improved. As Dr. Martin says, the principal obstacle to practical disinfection in Paris, has been the notification of the patient's disease to the health authorities. This arose from the unreasoning terror of some persons when confronted with the dread word "contagion." The only remedy for ignorance is instruction, and when people in Ontario learn how the contagion of tuberculosis is acquired they will not object to the systematic removal of the sources of that contagion. Physicians should frankly say that tuberculosis is contagious, but they should explain how, when and why contagion takes place. Information should be given the public about phthisis just in the same way as about scarlatina, typhoid fever or diphtheria. That this has been done of late is quite true. The medical press has teemed with articles on the prophylaxis of tuberculosis, and, as you are aware, important papers have been read on this subject by members of this Board. The ready response made in Toronto to a call for the establishment of a home for consumptives shows that the public taste has been influenced by the medical opinion. The Sanatorium for the consumptive has come to stay. Patients sent to Sanatoriums must, however, be those who are in the first or second stage of phthisis. Advanced cases would not be benefited by Sanatorium treatment and would probably increase the labours of the attendants, with a corresponding increase in the mortality statistics of these institutions. Such advanced cases will therefore be treated in their own domiciles or in an hospital. In the former case the civic health department should be notified by the attending physician, or in case no physician is called, by the householder, so that when the rooms are vacated the disinfectors may take possession and do the necessary work. In case the patient goes to an hospital or sanitarium, notice should be sent from the institution selected to the civic health department of the municipality to which the patient belongs, so that similar precautions may be taken. It is not possible to struggle successfully with an enemy like tuberculosis if the field of battle is enveloped in darkness. If hygiene is to do satisfactory work in reducing the mortality from tuberculosis the leading feature of the campaign must be prevention and the first and most important step in that direction is to apply the search-light of notification, after which disinfection logically follows.

THE PLACE OF SOCIETY IN DEALING WITH CONSUMPTION.*

By P. H. Bryce, M.A., M.D.

Your Excellencies, President and Ladies of the National Council of Women :

LADIES AND GENTLEMEN,—Some months ago, in Philadelphia, I presented a paper before the International American Public Health Association, whose annual meeting, I am pleased to know, is to meet in Ottawa in September next, on "The Place of the State in dealing with Tuberculosis," in which I endeavored to indicate by illustrations from methods actually existing in Ontario during the last twenty-five years, dealing with the insane, the feeble-minded, the aged and the sick poor, what I conceived to be the relations of state and municipal authorities to a disease which causes in Ontario annually some twelve per cent. of all the deaths, more than twice as many as all the deaths from the several other contagious diseases reported monthly; slays annually a total equal to three fifths of the total inmates of the seven Provincial institutions for the insane, whose exclusive demand for their yearly maintenance is \$595,843.13.

This disease of consumption has at the present moment, at a moderate estimate, 6,000 persons, adolescents and adults, within its grasp in the Province of Ontario, and will within the year have seen some 3,000 of them "Cross the bar;" while under present conditions at least 3,000 more of their comrades will have silently stepped forward to fill up the gaps, which this most fatal of weapons forged has made in the ranks, notably of those at an age capable of bearing arms. To-night, speaking as I do to an audience assembled under the auspices of an Association, the moral sense of the women,—indeed I might say the people of Canada, I shall endeavor to set forth the place which society itself, which elects and instructs her representatives, whether state or municipal, finally in all matters occupies in relation to this disease, which bears so heavily upon it, whether as an aggregation or as individuals.

In a very remarkable work entitled, "The Ascent of Man," by Henry Drummond, D.D., lately deceased, he has drawn a very neat and important distinction in relation to that problem of problems, the evolution of the world, of its inhabitants—indeed of society. Ever since Darwin's "Descent of Man," published in 1862, we have had set before us as the one "thing of life" and the condition of progress, viz.: the "Struggle for existence," and introduced into what we call Sociology it is the basis of the argument for the "Competitive system" which we are asked to recognize as the principle underlying all modern progress, and to excuse every form of individual or collective slavery, which grosser selfishness may cause to grow therefrom. Another law inevitably and unalterably associated with this which Drummond calls "The Struggle for the Life of Others"—the theory of "Altruism"—arises out of the fundamental functions of living organisms upon which existence depends. The two seen together appear in their simplest forms, viz., in the mother as nutrition, or the struggle for her own existence, and, if life or the race is to continue, equally the struggle by her to nourish and maintain life in her offspring. Hence "altruism," the very theory expressed in the words of the Divine Master, which have been adopted as the motto of the National Council of Women, "Do unto others as ye would that others do unto you," is being realized as having as scientific a basis as that other primal law, the struggle for life, both of which are indissolubly bound up in every complete scientific scheme by which society does not only exist, but struggles to evolve a higher life, a nobler ideal, a greater progress, whether viewed from the physical, material and commercial, or social and moral standpoint.

Without attempting to elaborate what I know this audience will agree with me in believing as axiomatic truths, it will, however, be of interest to us to apply these principles to the subjects under discussion to-night.

If we investigate the causation of disease we very soon discover that they have their natural history, just as do plants and animals, as have the rise and fall of inland streams, as indeed the flow and ebb of the tides. Cholera, yellow fever and malaria exist in countries where they may be said to be indigenous by virtue of the conditions of soil pollu-

* An Address before the National Council of Women at Ottawa, May 17th, 1898.

tion and organic decay in tropical climates; scurvy finds its victims within the sub-arctics where men are deprived of vegetable foods, and tuberculosis especially prevails in temperate climates, and in populous centres where imperfect nutrition and mal-nutrition are too often associated with the fierce competition, not for subsistence so much even as for wealth. Yet as plants and animals of one climate may be acclimatized in another, or may become extinct in their native habitat by the persistent pursuit of enemies, or by removal to another and unfavorable environment, so we find that cholera has again and again burst forth as an epidemic even in temperate climates, scurvy has appeared in tropical prisons, and consumption has become domiciled in the cottage of the settler planted on the illimitable prairie. In all life, therefore, whether of the disease germ or of man, we have the normal individual, the individual as affected by heredity, and the individual as influenced by his environment.

Keeping these seeming common-places before us, I think we shall be able to clearly comprehend why it is that the haunts of nature, as yet untouched, inviolate and free from the presence of the habitations of men, should be the sanctuary of health. Imagine the stream, the water-falls, the lake expansions of any one of the hundred tributaries flowing into your noble Ottawa, where through the long winter months snows of virginal purity have fallen to yield in the spring their crystal streams to the ever-green forests, over which the winds have blown for hundreds of miles, untrodden, save by the passing huntsman or lumberman, and we instinctively know that there no disease has yet been introduced, that there no infections are harboured, and there nature gives of her best and purest and without stint. All of us know this, for who amongst us has not spent at least some part of a summer holiday in these unbounded health resorts? All know the conditions, the converse of this!

Often has the picture of Prof. Teufelsdröckh, looking down from his attic at midnight over his city of Weissnichtwas as described by Carlyle, seemed to me the most dramatic and realistic picture of what he calls the phantasmagoria of human life. Says Teufelsdröckh: "It is a true sublimity to dwell here." These fringes of lamp-light struggling up through smoke and thousand-fold exhalations some fathoms into the ancient reign of night; what thinks Bootes of them as he leads his hunting dogs over the zenith, in their leash of sidereal fire? That stifled hum of midnight, when Traffic has laid down to rest; and the chariot-wheels of vanity, still rolling here and there through distant streets, are bearing her to halls roofed in, and lighted to the due pitch for her, and only vice and misery, to prowl or to moan like night-birds, are abroad; that hum, I say, like the stertorous unquiet slumber of sick Life is heard in heaven. Oh, under that hideous coverlet of vapours and putrefactions, and unimaginable gases, what a fermenting lies simmering and hid? The joyful and the sorrowful are there; men are dying there, men are born there, men are praying. On the other side of a brick partition men are cursing; and around them all is the vast wide night! The proud Grandee still lingers in his perfumed saloon, or reposes within damask curtains; wretchedness comes into truckle beds or shivers hunger-stricken into its lair of straw; in obscure cellars, Rouge-et-noir languidly emits its voice-of-destiny to haggard hungry villains; while Councillors of State sit plotting, and playing their high chess-game whereof the pawns are men! Gay mansions with supper-rooms and dancing rooms are full of light and music, and high-swelling hearts; anon, "Riot cries aloud and staggers and swaggers in his rank deed of shame; and the mother, with streaming hair, kneels over her pallid dying infant, whose cracked lips only her tears now moisten. "But I, mein Werther, sit above it all; I am alone with the stars." Perhaps! perhaps, ladies and gentlemen, it was for Teufelsdröckh, perhaps it may be for us, a true sublimity to dwell with him, sitting there above it all, alone with the stars, a correct enough attitude for a philosopher, but not, I trust you will agree with me, for men! The Divine Master looked down upon the Holy City to weep over it; thereupon he went down to the multitude and healed their sick.

Ladies and gentlemen, I have indicated as briefly as possible the several elements entering into the problem before us to-night. These are:

1st. A disease, the perennial scourge of the people.

2nd. The two laws which enter into all life, (a) The struggle for our own existence,

(b) The struggle for the existence of others.

3rd. The dependence of specific forms of disease, such as tuberculosis, which are but minute forms of life, parasitic on high beings, upon conditions of environment favorable or unfavorable for their development.

4th. The existence in the haunts of nature of an environment inimical to the spread of such a disease as tuberculosis.

5th. The presence down among men, as Teufelsdröckh looked upon them, of conditions favorable to the laws of growth and development of this scourge of our cities.

So important to the state, to the philosophy of life, to the science of biology, to the wholesomeness of nature uncontaminated, to the difficulties which beset man in his progress upwards to a higher and more complex social existence is each of these several elements in the problem that each might profitably occupy the whole time at our disposal in its discussion ; but I trust enough has been indicated to make plain to us that society, as it has evolved, as scientists tell us, from *homo alalus*—the savage with a language only of gestures and wild sounds, the denizen of caves, and perchance arboreal in his habits—to the Bedawin nomad, the shepherd with flocks and herds, thence to the man who cultivated the primal Eden, and there built the mighty cities, of that Mesopotamian land with their storied ruins, teaching us to-day of their greatness, and which the people of the continents have during the past half-century been unearthing,—has only been striving to attain to that high ideal of material progress and moral elevation, which is being foreshadowed in that Altruism, which, personified in its Divine founder, 1900 years ago, and emerging now and again in these centuries from the deep, like coral islands raised by their myriad minute builders, and like them only to be submerged again by some seismic disturbance of the social fabric, seems now to be gradually moulding society, after some regular and permanent form. We are discovering that true science is but a general term expressive of material progress, not alone of the individual, but of the nation and also of social happiness and moral and spiritual elevation.

“ For we know that through the ages an unceasing purpose runs,
And the thoughts of men are widened with the process of the suns.”

Let us examine for a brief moment what social progress means in this country, or indeed in any country ! Man with us has got beyond the stone age, though yet we have remnants of it in some of our native races. The settler goes forth, and in this new age, fells the trees and erects the rude log cabin. At a distance from him soon comes his neighbor. The local store springs up, and near it the mill, on some convenient stream. Hence a village with its smaller lots, its aggregate of individuals. The cabin large enough for two soon has its half-dozen inmates. Soil-pollution gradually increases about the dwelling, the springs become polluted by animals and men. What to the nomad was impossible, now prevails, viz., the danger of permanent settlement. The village grows into the town. Better houses, some attempts at outward adornment, street building and walks follow. Here and there the spring or well is cared for ; health is retained. But soon the diseases of aggregation, as typhoid fever, appear indoors the crowding means polluted air, aerial infection from some imported cause of disease, as diphtheria, or perchance consumption, is inevitable, and the family, indeed the very house, becomes a source of public danger. Probably the most notable fact in the development of such settlement, where the schools and churches early appear, is the relative absence of the social idea of co-operation in the matters of health, or indeed in any true sense of the word of the possibility of such. For years it has been my fortune to visit settlements in every part of the Province, and constantly have I found, that while they may be informed and instructed in all the details of some political convulsion, though they may argue with all the virulence of an *odium theologicum*,

“ Of forms of faith let priests and bigots fight,”

yet I have known no longer than last year, a rapidly progressing town of 4,000 with miles of fresh water lake laving the very shores of the town site, continuing to contentedly bail water into barrels from the polluted bay, receiving the filth of the town even ; although some fifty cases of typhoid had appeared in the town within a previous two months.

Churches, schools and opera house, even an hospital to receive their typhoid patients, and a splendid Queen's jubilee celebration, and yet such polluted water was given to their own people and to the travelling public, waterworks being only talked of.

Or I might take an example of one of the oldest, busiest, and wealthiest manufacturing towns of western Canada, where thousands of dollars were being spent on granolithic sidewalks, which had limestone rock near the surface, and the water from a stagnant mill-pond on the high ground soaked into the cellars of the main street, so that even in August barrels continued to float in them.

Or to take one of the larger and more rapidly growing cities in the eastern portion of the Province, with wealth, educational and religious institutions, and social brilliancy at their highest, a city which within the past five years has added more than 100 acres to her area, and yet which has again and again refused to vote public funds for a sewerage system, which alone will enable hundreds of houses over this area to have one of the primary requisites to good health, a dry cellar. Last year this city spent very largely on her charities, has at least half a dozen hospitals, has sweetness and light and legislation, yet spent but a few hundreds on public sanitation. In the words of the apostle, "Brethren, these things ought not so to be!" Perhaps it will be impressed upon some of the members of the National Council here to-night that there is here a field for a womans' sanitary protective association.

There is, however, another most interesting and important phase of this modern social evolution. I have pointed out that a dry cellar and well-drained house are the simplest elements entering into the healthfulness of a dwelling. They prevent dampness and decay with their associated dangerous emanations. But while in many houses the superstructures are well built and productive of health, we have in our schools and workshops conditions demanding constant and systematic supervision. We in Ontario have much to be proud of in our school system, and indeed of our school buildings. But when we realize that in the city of Ottawa the yearly natural increase of births over deaths, allowing nothing for immigrants, means the need for the erection annually of a new school building for some 300 scholars and seven additional teachers, it will be understood that a broad and intelligent policy is demanded if we are to at all adequately meet the requirements.

Not excepting the home, where the child's first years are spent, we have in the school, where six hours a day are spent, one of the most potent influences for good or evil present in our social life. Rapidly as we are overcoming these difficulties, it is nevertheless true that some 75 per cent. of all contagious diseases are contracted through the medium of schools, while the directly malign influences of the foul air, due to overcrowding, can be seen by the most unobservant who will follow the health of his child during a school term. Parenthetically it may be remarked that female school teachers of the London (England) board schools have shown a higher mortality than almost any other class between the ages of 20 and 39.

Of this class of evil is the over-crowding of workrooms and factories. Municipally, as yet, we have done almost nothing to regulate this class of evil. Here, however, competition enters in and we are told that if the employer and the employed are agreed nothing more is to be said.

In this connection we have that other question to which we have only begun to give attention, viz, the systematic inspection of our food supplies. Is anyone seeing that the milk and meat in our markets are from healthy animals? Manifestly such supplies demand careful and constant supervision.

But I do not need to push further illustrations of the complex factors which enter into the social life of man, advanced as he has from the stage of a nomad for whom nature was the sanitarian. It is very plain that with social elevation develops the necessity for and *pari passu* with it mutual co-operation. First the cooperation is within the family, then between neighbors, next it is the community, then the town, the city, the province, the nation! And now during the balance of time at our disposal I purpose to show where this essential feature touches our lives.

In this brief tracing of society from its simpler to its more complex forms, we have been able to recognize very clearly that the very process tends to produce conditions and an environment which vary in character or degree from those normal conditions in which man, as do plants and animals, resists best the forces inimical to his healthful growth and development. Gradually acclimatization goes on, but through infinite pain. Tennyson's words are most true :

"So careful of the type she seems,
So careless of the single life!"

We have something of the change of physical environment from country to city. Teufelsdröckh has pointed out how social and moral environment are equally potent in their effects. Without, however, dwelling on those influences which have caused within recent years a new word, "Neurasthenia" to be coined, we find them expressed perfectly in a condition which every person present must recognize as that of innutrition, or otherwise malnutrition. The hurried breakfast of the working girl—often, alas, after a night of insufficient sleep, for she too must have her social pleasures,—the cold lunch at dinner hour, associated with the air impurities of work-room, or in other cases of school and home, all tend inevitably to produce, with over study in some cases, and social dissipation in many more, the one dominating condition, that of anaemia, which, indeed, in many instances in the healthy and superadded to hereditary weakness in others, makes thousands annually amongst what Professor Verneuil characterizes *les candidats de la tuberculose*. At the risk of seeming to deal with matters too technical for a popular audience, I shall attempt to make this physiological point plain, owing to its importance in dealing with the practical phase of the problem before us, by an illustration taken from the experimental method of him, the immortal Pasteur, whom his fellow-workers and all his disciples reverently call *Le Grand Maître* of biological science.

Some of my audience will know that practically the first disease shown to be due to a microbe was anthrax, a disease which annually caused many thousands of deaths in cattle and sheep in France, but which, since Pasteur discovered its vaccine, has notably decreased, with a saving to the state of 7,000,000 francs. Now, in studying this disease, Pasteur found that he was easily able by injecting a few drops of a solution in which he had grown the anthrax germ to rapidly produce fatal disease in oxen, sheep, rabbits, and guinea pigs, but that he could never produce fatal results in fowls. Greatly puzzled, he studied the germ still further, and found it was sensitive to an increased temperature, and would not grow in the blood of fowls several degrees higher than of these other animals. Now mark the beauty of the inductive method! He immediately thought, "If I reduce the temperature of the fowl it ought to grow," and he caused a fowl inoculated with the germs of anthrax to stand in cold water so that its temperature was reduced from 42°C. to 38°C. At the end of forty-eight hours the bird was dead and its blood was found to be teeming with the microbes of anthrax. Other fowls after inoculation and similar chilling he wrapped in cotton wool and flannel where they gradually regained their normal temperature and recovered and no microbe could be found in their blood.

I trust the inference is evident. The so-called candidates for consumption, like the fowls, once perhaps normally resistant to disease, lose this in the degree that their vital powers, their richness of blood, their ability to obtain, digest, and assimilate food are reduced and lessened; and while, should the microbe of tuberculosis not be present in their respiratory passages or stomach, they will not take consumption any more than the fowl without inoculation would not take anthrax, yet it is evident that malnutrition, temporary exhaustion, a severe chilling, or a severe sickness, as typhoid fever, all create conditions most favorable for the attack of a disease whose germs are so generally disseminated in the habitations of populous centres. To use the accurate expression of Verneuil, "The changes of environment exercise a notable influence on the development, the march, and the termination of tuberculosis. These changes operate in two ways, from the city to the country (emigration *urbi rural*); from the country to the city (emigration *ruri urban*). The first renders great service to the tuberculized, the second favors on the contrary the appearance or progress of tuberculosis."

Surely, ladies and gentlemen, very manifest facts are before us ! We have a disease shown to be by far the most fatal to our people ; to be a disease due to a specific germ or microbe ; to be essentially dependent for its development upon mal-nutrition, whether hereditary or acquired ; to be dependent for its development upon an environment, essentially caused by density of population, whether localized in a single house or in many houses as in a city ; and by such other conditions as by affecting nutrition and nerve force, lessen the vital resistance of the tissues to the growth and development of the disease.

I may ask, adopting a phrase from, I believe, a certain political vocabulary, "What are we going to do about it ?" Is it hopeless to attempt the solution of the problem ? Some may be inclined to say "It is the will of Allah," but the science of to-day looks upon no problem of nature as insoluble.

Fifteen years ago, Ontario had but twelve public systems of water supply and over 3,000 deaths from typhoid fever in five years ; in 1897 she had ninety systems of public water supply in her cities and towns, and but 1,600 deaths from typhoid in five years then ending. Even with the still high mortality Glasgow has seen a falling of the deaths from consumption between 1860 and 1894 of forty-four per cent, due to improved sanitation. With such facts regarding the disease in Glasgow, and still more remembering what has been done regarding typhoid in Ontario in fifteen years, I am prepared to say that given the full knowledge of the cause and conditions of the development of tuberculosis, and fifteen years will see the death rate from this disease in Ontario reduced as much as typhoid during the past fifteen. And why dare I say this ? Primarily because science has solved the problems of the cause and prevention of the disease, and secondly because society, the State, and greatest of all the National Council of women who represent the moral and intellectual will of the people of Canada, realize to-night that there is a practical means whereby early and effective aid to recovery can be brought to the many in our communities, who hitherto have been looked upon as condemned to certain death ; and at the same time such may be saved the sad consciousness that in going down to death they are likely to drag other dear ones with them. Elsewhere I have quoted statistics taken from mortality returns in England, and such as those from the New York Health Department which state that in a single crowded ward in that city in 1896, thirty-seven per cent. of the total 663 houses were infected with one or more cases of consumption, or there were .81 per cent. of cases for every house in the ward. But it comes nearer home when I state that during ten years, of the total deaths in a single old-settled county of Ontario, thirty-seven per cent. of all persons dying of consumption were names which recurred on an average two and one-half times, and the same family name in the highest instance occurred seven times in ten years.

Let these facts both of the danger and the possibility of remedy in this disease be once fully realized by our people, as they have for years understood the dangers of spreading small pox, and to-day of diphtheria, and, in spite of the chronic course of this disease and its relatively less contagiousness, can any one doubt that in the degree which the individual, the family, the municipality, and the state appreciate the preciousness and economic value of a life or the lives of its citizens, each will put forth in its place energies adequate to meet the needs of the case. If it be asked upon what is such reasoning based, I say simply from analogy based upon facts already within our knowledge.

Sixteen years ago there were no laws in Ontario for systematically dealing with contagious disease, or the control of public water supplies. To-day in the 747 municipalities there are 5,000 men appointed by law, who, nominally at any rate, and in very many cases actively, are engaged in dealing with public health matters, apart entirely from the regular physicians. During this period some \$9,000,000.00 have been spent in the construction of water works in ninety municipalities.

But further, twenty years ago there were but ten hospitals in Ontario receiving Government aid for 4,372 inmates ; in 1897 there were forty-seven hospitals and 19,372 patients receiving Government aid.

In 1880 there were two County Homes for the poor in Ontario; in 1897 there were fourteen; and where in 1880 there were twenty-three Refuges and Orphan-ages in the cities and towns, to-day there are forty.

Again, while in 1882 there were no contagious disease hospitals and very few separate wards for their treatment, there are to-day twenty-five contagious hospitals or separate wards in other hospitals regularly maintained for contagious diseases, while other smaller towns have buildings fitted up as temporary hospitals.

Even up to five years ago, and in some instances to-day, consumptives were treated in the general wards of our hospitals; to-day every new hospital and many of the older are preparing to place consumptives in separate wards.

Thus it will be seen that there has been a steady evolution toward the true scientific method going on in every one of these problems. The state and society have in their methods followed very closely upon the facts established by the experimental methods of science. The poor are rapidly being taken from the gaols and placed in rural Homes, and the street waifs in Industrial Schools. Small-pox, scarlet fever, and diphtheria are taken to contagious disease hospitals; and lastly, the consumptive is being placed in a separate ward. But at last and recently the next great step has been taken, and this time, as in most other cases, first by private philanthropy. As the evangelical Van der Broech was the first to establish near Hamburg the idea of the free colony for the unemployed by his school for boys and subsequently girls, and as pastor Kräenbuhl, the evangelist of Bratenberg, through noting the difference between those mountaineers of the Swiss Alps and the degenerate and physically weak who were in the schools of Berne and Zurich, was led to place a number of these street arabs in a school in the mountains, and saw that within a few months they were metamorphosed, and so was the originator of the mountain cure for consumptives in Switzerland, so twelve years ago private philanthropy established the Trudeau Sanitarium for Consumptives in the Adirondacks of New York State, and 1897 saw the Muskoka Sanatorium for Consumptives similarly established.

Surely this *resume* of the evolution of altruism in society and of state socialism, as governmental interference in social matters is called in Germany, in Ontario, and elsewhere is enough to authorize the statement that the movement for "Homes for Consumptives" now begun will see a rapid evolution in Canada within the next fifteen years. And the reason for them is simply that the situation demands them.

It is fifteen years since a report presented by its committee to the Social Science Congress of Great Britain on "Administration of Hospitals" stated, "There is a class of illness, which, refused admission to hospitals, is unsuited to work-house infirmaries. Such diseases are consumption, hip disease, and other chronic ailments requiring a lengthened treatment, country air, and surgical appliances are almost entirely neglected. Medical relief to be complete should effectively deal with these." This statement made so many years ago has had emphasis added to it every year since, and nowhere more than by the single fact that of 430 consumptives treated in the hospitals of Ontario in 1896, twenty-three per cent. of them died in the hospital, although their average residence there was less than fifty days. In other words they went to the hospital really to die.

Clearly then if the needs of the case are proven there only remains for us to show that a remedy has been found, and that there are practical means whereby such remedy can be provided. These are:

1st. Fight by all combined energy to prevent by education of the people and by legal enactments every cause inducing ill-health and thereby consumption. What these various causes are I have already indicated.

2nd. Assist in the removal of the cases, the sources of immediate infection, at the beginning of the disease from the small and poorly equipped homes and the factories and work-rooms where our less fortunate people reside and labor.

3rd. Build in every county or district "Homes" where at the early stage of this disease, when it is essentially one of malnutrition, those suffering may go, and by correct regimen, abundance of food, of fresh air and sunshine, of exercise, rest and sleep, main-

tain the fight against the destructive forces of the disease ; where they shall have a fair chance of saving their lives to their families and to the State, and at the same time be saved the danger of infecting those whom they love.

Take but a single example of what this means in a single city. From the Toronto death returns of 291 names of persons who died in 1896 of consumption 184 were between 15 and 60 years of age, and of these 52 were returned as "housewives." To none of us is there in the misfortunes of life any occurrence which seems sadder or which appeals more to human sympathy than the loss to children of a mother's care. Sadder still is the thought that through extending this to them to the last moment of her life she in many instances has become the innocent medium of communicating the seeds of this fatal disease before she has left them.

To see such "Homes" erected then must be the object of our efforts. How have the 47 general hospitals of Ontario been established? In almost every case by the efforts of the ladies of our cities and towns, supported by private subscriptions, and grants made by the municipal councils, supported by government aid. We have a large and most influential association called the Prisoners' Aid Association, which is ameliorating the condition of these unfortunates and getting many vagrants removed from county gaols to Houses of industry which they insist shall be established. Is the end to be attained not great enough to have, not necessarily a "Consumptive Homes Association," but the local councils of this association to make this scheme one of their chief fields of operation during the coming year. The Provincial Board of Health which I represent has for years been exerting its influence and not in vain to educate the public on the various phases of the causes and prevention of this fatal disease. It is to-day ready to aid by literature regarding desirable locations, method of construction, equipment and management, and is trusting to find allies, especially in this association, who shall bring local influence to bear in a matter which always has to have a local committee of "ways and means" in order to obtain results. I am further empowered to say that the Minister having under his charge the Provincial Department of Health is prepared to lend his influence to second in every way at his command the local efforts made for the progress of the work of establishing such "Homes."

At Christmas time in Toronto when I addressed the Local Council of Women on this subject Her Excellency promised the work her countenance and active assistance. In inviting me to speak to-night to the ladies of Canada she has indeed done more than this, for she has given me a chance to appeal to the hearts and the charitable philanthropy of the women of a whole nation. With these combined influences actively at work, seconded everywhere by the leaders of medical science in Canada, and supported by municipal and governmental aid, I already see the dream of many years fulfilled, and the greatest advance made which is possible in any field of Public medicine.

RELATIONS TO AND DUTIES OF MUNICIPAL AUTHORITIES REGARDING SANATORIA FOR CONSUMPTIVES.

An Address by P. H. Bryce, M.A., at a Public Meeting in Toronto, Dec. 12th, 1898.

MR. MAYOR, LADIES AND GENTLEMEN—Viewing the subject which is especially engaging our attention to-night from the position of a public officer, whose duty it is to study the causes of and to advocate measures for the prevention of disease, I have no hesitation in stating that in my opinion we have before us at once the most important and the most difficult problem which we as members of a complex society are required to deal with, viewed either from the social, the scientific, or the economic standpoint. We have to enquire into the manifold influences, which, year by year, cause almost one-seventh of the deaths in the population of our country and our city to result from the attacks of a single disease, manifesting itself in different forms, and to answer the question of whether we have not enough scientific knowledge of its origin and modes of progress as to be able to institute organized measures for its prevention or cure.

There has been placed in the hands of many who are present to-night a list of every death registered as due to tuberculosis which has occurred in our city during the years 1892 to 1897 inclusive, classifying these deaths by ages, sexes, and occupations; and a similar list, telling much the same story, can be made for every city in the land; and a still larger list, proportionately, for all the great cities of America and Europe.

First we observe in this list that a total of 2,290 deaths occurred, or 450 annually on an average. Of this total 404, or rather more than one-sixth occurred in the first year of life, caused by hereditary taint, unwholesome or tuberculized milk, infection from tuberculized mothers, and infected houses. Other 333 deaths occurred between one and fifteen years of age. The rest, 1,553 or more than two-thirds of the whole, occurred above this age; and nearly all, 1,421, between the ages of fifteen and sixty, or during the active wage-earning period of life, when lives are worth most to the State and their families. Indeed, were we able to exterminate this disease, we would save one-third of the deaths from all causes during this period, since comparative statistics tell us that consumption causes 37 per cent. of all deaths in the cities of the temperate climates of America and Europe between these years.

Second we further find that of the 1,555 deaths over 15 years, 191 occurred between 15 and 20; 256 between 20 and 25; 271 between 25 and 30; 214 between 30 and 35; 182 between 35 and 40, and 97 between 40 and 45. That is, 1,211 persons died during the years, when if married they would be rearing families.

Third, examining the list as to occupations we find 221 registered as housewives, of whom 168 were between the ages of 15 and 45, or 75 per cent. belong to the child-bearing period. Assuming all to have been mothers, they must have left behind them families of children averaging two at least in number, all young, many indeed being babes. To this list we have to add almost as many more in the list of those whose occupation is not given, or some 80 young families are left motherless every year in Toronto from this disease. A similar number of young families are left fatherless every year to swell the unfortunate number.

Fourth. If we investigate the table yet more closely and examine the occupations, we will find that at least 80 per cent. or four-fifths belong to our artizan and laboring, or wage-earning, class. Need I say what follows when the bread-winner ceases work and becomes a care instead of a help in a family? And what of the family when he or she is gone?

Fifth. Turning to the tables found in the government reports, we find a partial answer to these questions. In Toronto we have 8 orphanages, so classed in the reports. In 1897 these together had in residence 847 children at the beginning of the year, and during the year had let the most of them go for adoption or elsewhere, I know not where, but 812 more were admitted. Two regiments, each 400 strong, then are annually marched to our orphanages, most of them the indirect victims of this disease. Surely we have absolute proof in this that the disease reduces to the extremes of poverty our honest and industrious working classes

Sixth. But what more do we find in these tell-tale government blue-books? This, viz:—that 19,617 persons were inmates of Provincial hospitals in 1897, or 2,100 more than in 1896, and of these 6,009 were in Toronto, the increase being 517. Were any of these consumptives, who, no longer able to be maintained at home, were sent to the hospitals at least to die in comfortable surroundings? This is what the reports tell us: viz., that in the five hospitals of the city some 369 cases of tuberculosis of the lungs and other organs were treated in 1897. With regard to the total diseases treated in the out-patient departments of our hospitals, I find it difficult to obtain the complete figures, but so far as I have received them they are as follows:—General Hospital 14,549, Sick Children's Hospital 3,366, St. Michael's Hospital 6,789.

I am only, ladies and gentlemen, in the brief time at my disposal, dealing with figures which are available to every one of you. The large-hearted philanthropy of the citizens of Toronto, of her municipal government, which between charities and health department spends \$90,000.00 annually, and of the Province of Ontario which spent last year

in Toronto \$42,998.60 make our own hospitals what they are, and have long been, our glory, and to our credit as a city. But need I ask you whether it has been wise philanthropy and good economics which have saved in 1897 as compared with 1891, 230 lives from scarlatina, diphtheria, measles and whooping cough and from small-pox? Have we not these sturdy, growing children—our future wage-earners—saved to us, and homes made happy by their laughter? If you agree with me in this, then a hundred times more must you agree with me that we must apply our energies, our time and our money to saving three times the number of lives of all those who died of these several diseases, from a disease which robs us of 300 wage-earners annually, makes us support 800 orphans, and sends hundreds into our hospitals, to die at least in decent surroundings.

Could we on the New Year's Day of 1899, give a home to the thousand persons at least, who at the present moment are tuberculized and living in Toronto; give to the many in the initial stages of this disease, a chance of life by sunshine, food, rest or regulated exercise, and we would find a year hence our list of able workmen increased by several hundreds, over two battalions of orphaned children reduced by one-half, the inmates of our hospitals and homes lessened, and our general happiness and prosperity notably increased.

It simply means transferring our energies and our funds to preventing what in all these several ways we are endeavoring at an enormous cost to ameliorate. I ask you, ladies and gentlemen, in the name of our suffering fellow citizens, in the interests of our national well-being, in order to enlarge the knowledge and power of science to prevent disease, and from the standpoint of ordinary prudence and common sense to take the first step to this end by establishing a citizens' sanatorium to cure consumption, and by removing the infected from the houses of our poorer people to prevent further spread of the disease.

But some one asks, is such saving of life possible? Can consumption be cured? Our answer is, such saving of life is possible. Consumption can be cured. But at what stage? I answer at the same stage when so many of our other severe, contagious diseases are curable, viz.: in its initial stage, early in the onset of the disease. Abundant statistics are available to prove that this is true. Dr. Weicker of Gorborsdorf, of one of the oldest and largest sanatoria in Germany, states in his latest statistics that there have been eighty per cent. of established cures amongst the poorer class of patients sent by government insurance societies, with an average stay of but sixty-seven and one-half days. This marvellous result is due to the fact that these societies send patients at the earliest possible date. But taking the results of the Adirondack Sanitarium in New York State, now established thirteen years, for 1896 I find that 177 patients were in residence for various periods. Of the eighty-nine patients who remained from three to twenty-five months, or an average of eleven months and ten days, eighteen were incipient cases, of which fifteen were apparent cures, and three had the disease arrested; forty-five were advanced cases, of which five were apparent cures, and ten had the disease arrested; twenty-five were far advanced cases, of which none were apparent cures, and seven had the disease arrested. Thus the point of greatest interest is that, of the eighteen incipient cases, eighty-four per cent. left cured.

But the life saving is especially to be recognized in the fact that these were sent for cure at a period in the disease before they were a serious menace to the health of their families. Statistics innumerable might be quoted of whole families swept away by this disease, but many present are familiar with several so recent illustrations in our own city that further illustration is not necessary.

Ladies and gentlemen, we have as fellow-citizens a present, urgent, imperious task laid upon us of lessening the misfortunes and sufferings of our working people, increasing the general happiness and prosperity, and removing serious danger to ourselves. Shall we not perform it?

PRACTICAL RELATIONS OF STATE HEALTH AUTHORITIES WITH RAILWAYS AND OTHER PUBLIC CARRIERS IN THE MATTER OF THE TRANSPORTATION OF CORPSES.

By P. H. Bryce, M.A., M.D., Secretary Provincial Board of Health.

TORONTO, July 10th, 1898.

Mr. President and Members of the Association of National Railway Surgeons of America :

GENTLEMEN :—In dealing with the subject upon which I have been asked to prepare a paper, it is necessary that we recognize several conditions which during the past twenty-five years have changed in the matter of the transportation of the dead, and which affect very materially the relations of public health authorities to this matter. The first of these is the enormous development in the facilities to transmit freight and express parcels of all kinds by rail, both as regards time and expense. 2nd. The well-determined cause of the origin of the principal contagious diseases, and of their methods of dissemination, and 3rd. The development along with such knowledge of the scientific means whereby the infectiousness of such diseases may be wholly or in a great part limited. Formerly the limited amount of travel between different sections of the country, the time and expense involved therein, necessarily made the number of persons dying away from home less than at the present time ; and the question of their transportation home, owing to these several reasons was a matter which would only occasionally be discussed. To illustrate how common the transportation of the dead has become at the present time, I give sub-joined the returns supplied me by the kindness of Mr. Quick, the General Freight Agent the Grand Trunk Railway : viz, of corpses shipped per G.T.R. May (1898) 151, and June, 95. With such every day facts before us, it is evident that the social sentiment of our American communities tends to conform with the old idea, that members of families dying abroad, should be buried at home. As regards the transportation of bodies dead from contagious disease which necessarily becomes a question with which health authorities everywhere have to deal, it is apparent that the facts known for so long a time that contagion spreads from such bodies, necessitated the absolute prohibition of their transportation as the only means formerly known whereby public interests in matters of health could be considered. This may said to be simply an illustration of what was formerly known as a "shot gun" quarantine in dealing with outbreaks of small-pox, cholera and other similar contagious diseases. To-day, however, it may be said that as in all States and Provinces where State medicine has become developed, these old methods have largely given way to a more intelligent and effective scientific quarantine, so in the matter of the transportation of the dead, we now must recognize the ready limitation of the spread of such diseases by the use of simple, yet thoroughly scientific measures, and the only question which would seem to remain for our consideration, whether as State Officers, Municipal Officers or Railway Surgeons, is, what practical organization is available for putting such methods into effect. There are three factors necessary for the solution of this problem, state and municipal regulations with authority and machinery for their proper execution, railways willing and prepared to carry out their share of the work, and the undertaker or person representing the individual of the community whose duty and desire is to see that his dead are buried, both in conformity with his wishes and the regulations of the State. In practice it may be said that no machinery, theoretically perfect in regard to dealing with contagious diseases, has always proved equal to the work to be done. To-day in several States, possibly in one or two States, the undertaker or embalmer is licensed, and by such license is assumed to be trained in all modern scientific methods for preparing dead bodies for transportation without danger to the public, and to be of such good standing in the community that it may in this particular trust its health to his care. For instance, the City of Chicago has licensed embalmers, divided, I believe, into grades, and upon these individuals the Health Department depends, along with the physician who has attended a patient who has died, for the safe carrying out of regulations, for the safe transportation of contagious disease. The following two communications illustrate what may happen occasionally, though perhaps not frequently as a result of dependence on such persons.

A letter of Dr. Sheard, M.H.O., Toronto, regarding scarlatina brought from Chicago.

TORONTO, April 12th, 1898.

Dr. Peter H. Bryce, Secretary Provincial Board of Health.

DEAR DOCTOR,—We have had a case of Scarlet Fever reported No. 53 Borden St., in the family of one Crompton. My Inspector on looking into the matter informs me that Alice D. Crompton, 3 years of age, came from Chicago on April 7th, and on April 9th was taken with Scarlet Fever and removed to the Isolation Hospital.

On March 24th. Guy and Marion Crompton were down with Scarlet Fever in Chicago, and attended by one Dr. Porter. Guy Crompton died on April 5th, and a certificate was given by Dr. Porter, of "Heart Failure." The body was brought on from Chicago and interred in Toronto on the 7th April. Marion Crompton is at present in Chicago and ill with Scarlet Fever. The Inspector was informed by the Crompton's that Dr. Porter gave them permission to come to Toronto.

In view of the trouble which we had with Scarlet Fever in the City of Toronto last summer, and the extreme liability to the spread of the infection, I think these facts ought to be presented to the Health Commissioner of Chicago, and with that object in view take the liberty of writing you in reference thereto.

Faithfully yours,

(Sgd.) CHARLES SHEARD, M.D.,
Medical Health Officer.

Dr. Bryce's letter to Dr. Reynolds, health officer, of Chicago :

TORONTO, April 13th, 1898.

Dr. Reynolds, Commissioner of Health, Chicago, Ill. :

DEAR DOCTOR,—I send you a copy of a letter I have received from Dr. Sheard, Medical Health Officer, of Toronto, regarding the appearance of scarlet fever, in a family reported as recently having come from Chicago. The cause of the transportation is apparent in the report of the physician, which gives "heart failure" as the cause of death. I shall be greatly obliged if you will have the facts enquired into, as to whether the child, Guy Crompton, who died April 5th, had been reported to your department as a case of scarlet fever. As you are aware, a representative of the State Board of Illinois attended the conference at Cleveland last June, where we were discussing the transportation of corpses by rail, and while the general feeling was that we wished to encourage transportation under proper supervision, it is clear that we must have such dependence on our undertakers that they will not be guilty of such violations of the law as that reported by Dr. Sheard.

Your obedient servant,

(Sgd.) PETER H. BRYCE,
Secretary Provincial Board of Health.

Dr. Reynold's reply :

CHICAGO, April, 1898.

P. H. Bryce, M.D., Secretary Provincial Board of Health, Toronto, Ont. :

DEAR DOCTOR,—Your letter of the 13th inst., with an enclosure from Dr. Sheard with reference to the fact that Alice D. Crompton, three years of age, was taken with scarlet fever on her arrival at Toronto from this city, and the fact that the body of Guy Crompton was shipped to Toronto with a shipping permit showing the cause of death to be "heart failure," when in fact it was scarlet fever, is received.

Enclosed you will find copy of the death certificate filed in this office, which shows that the death was from scarlet fever, heart failure a contributing cause. You will also find a copy of the report of Dr. Gunn, Inspector of Funerals, and a report from Jas. J. Dillon, the Recorder of Deaths. From these reports it is evident that the body was properly prepared, and the cause of death given was scarlet fever and not heart failure. We must, of course, admit that Alice Crompton should not have been allowed to travel from a home where scarlet fever existed. I have not yet heard the full particulars from Dr. Porter, but an investigation is in progress, and he will be dealt with if we find he sanctioned the trip.

It is our custom to permit the attending physician, where he assumes to prevent the spread of a contagious disease, to have charge of the case. As a rule it works admirably. At present, however, it looks as though Dr. Porter had rather betrayed the confidence reposed in him.

I thank you very much for the information contained in your communication, and I am very glad to see that my native Province is taking such excellent care of the health of its citizens.

Kindly commend me to Dr. Sheard, and believe me,

Very truly yours,

(Sgd.) ARTHUR R. REYNOLDS, M.D.,
Commissioner of Health.

Dr. Bryce's reply to Dr. Reynold's letter :

TORONTO, May 3rd, 1898.

To Arthur R. Reynolds, Comm. of Health, Department of Health, Chicago Ill. :

DEAR DOCTOR,—I have to thank you very much for your letter of the 18th ult., regarding this matter. I have sent Dr. Sheard a copy of your letter, and trust that the matter has been satisfactorily explained.

Yours very truly,

(Sgd.) PETER H. BRYCE,
Secretary.

It will be quite apparent from this illustration that health authorities in granting that modern methods for the transportation of persons dead from infectious diseases are sufficient to protect the public health, and assuming that the persons, whose municipal authorities permit them to do this work of the preparation of the dead may be depended upon, must recognize that local conditions are much too varied for absolute trust to be placed in the thoroughness of the knowledge and work of undertakers taken as a class. Notwithstanding this fact, the public health authorities of different States and Provinces on the continent have by reports adopted at different meetings, recognized that the resolutions which were the outgrowth of the Conference held in Cleveland in June, 1897, between State Officers of health, Railway authorities and representatives of the Undertakers' Association are, if properly carried out, adequate in their judgment to the protection of the public health and for complying with the deep-seated social sentiment already alluded to.

For the convenience of members of the Association who may not have seen these regulations, I include them herewith. I may say that these regulations have, so far as Ontario is concerned, been approved of by the Provincial Board of Health, and only await the approval of the Lieutenant-Governor and his Executive in order to become law.

In the report of the Provincial Board of Health, which adopts these regulations, there is however, a very definite line of action deemed necessary for their proper execution. The report states :

(a) With a view to giving effect to these regulations, your committee has attempted to give practical expression to the views of your Board as expressed at the last meeting. In order to insure proper care and preparation of the bodies of the dead, prior to transportation, it is proposed that for the purposes of these regulations, the seventeen divisions into which the Province of Ontario is divided, for returning representatives to the Ontario Medical Council, be adopted, as the units for which one or more certified persons may be appointed to carry out the foregoing regulations of the Provincial Board.

(b) In order that persons certified may be fully qualified to carry out the regulations, your committee would suggest that examiners nominated by your Board be appointed, before whom candidates shall be notified to appear from the several divisions, and that in accordance with their standing on examination, they shall receive a certificate of qualification.

(c) In order that the greatest control may be practised in cases of dead bodies prepared for transportation, it is recommended that there be but one person named in each of the seventeen districts, who would be a resident in the district.

(d) In order that the matter may be properly regulated as regards expense, the Board would prepare a schedule in which would be included the cost of the travelling expenses, and of the preparation of the body for transportation ; while at the same time a provision would be inserted in the regulations governing the appointment, whereby a disputed account could be taxed in the matter of costs

(e) It would further be necessary to provide that a certified appointee could engage in work beyond his own electoral division only at the request of the appointee for such latter district, or in the case of the sickness or death of any appointee or in other emergency, the power to allow the passing from one district to another might rest with the Secretary of this Board. The latter methods to be alluded to by me further, with regard to the subject I present to you for discussion. To-day, practically no bodies dead of contagious disease, are transported by the railways of either the United States or Canada, and it must be apparent to the six hundred members of this Association, that where some 60 States and Provinces have a common railway system, where thousands of municipalities with their officials exist in these different States and Provinces, and where hundreds of railways exist under different management, that the State officer if he admits the practical possibility of transporting persons dead of contagious disease without endangering the public health within his jurisdiction, has to feel that there is behind him a common organization which is prepared to protect his public against the many possible accidents, which such diverse communities and interests involve. It may appear to the members of

this Association, that the time has practically arrived when such an association of trained scientific gentlemen exists, upon whom such a State officer can confide, viz.:—The Association of National Railway Surgeons, whose interests, it may be said, are those of the Companies they represent; but it might be that such gentlemen would at times fail to conform to regulations which might be detrimental to the temporary interests of their Company. I recognize on the other hand, however, by virtue of the scientific status of the members of this Association that they will require State officers to recognize that the best interests of the railways are consulted by the closest conformity to a system of regulations which ought certainly to be uniform in practice.

What can the members of this Association do to assist public health officers in this matter? I would say by advocating in those communities and States from which they come, by their most earnest efforts, the appointment of a number of expert and scientific members of the medical profession who shall be responsible to the state authorities for supervising the preparation in every case of the bodies of those dead of contagious diseases within their jurisdiction both within and beyond state boundaries, for transportation. There need not be many such, since it has been estimated that out of one thousand deaths in Ontario, dead of contagious disease, probably not more than 50 would die away from home. If such officers could be called upon by the undertaker in charge of the arrangements for a funeral, they would proceed to such point within their jurisdiction, supervise the preparation for transportation, and forward as is provided in the proposed Act and Regulations, a copy of the Transit Permit made in duplicate, to the central Health Officer of the State. By this simple method it appears that such regular control of the transportation of the dead over the whole continent becomes possible, since it will make it a simple matter to trace any unfortunate results growing out of any particular case immediately back to the responsible party.

I trust that this Association will give to this subject, not only such discussion as its importance deserves, but will by resolution and in such other way as it can, aid in bringing into practical effect, a work in which the Companies they represent are so greatly interested from the financial standpoint in the community they live in, and still more greatly interested from the public health standpoint.

REPORT ON THE IROQUOIS WATER WORKS.

April 19th, 1898.

By P. H. Bryce, M.D., Secretary Provincial Board of Health.

To the Chairman and Members of the Provincial Board of Health:

GENTLEMEN,—In consequence of the information contained in the correspondence herewith submitted between Dr. Harkness, Chairman of the Iroquois High School Board, and your Secretary, and of the results of the analyses of samples of water being supplied at the time thereof to the villagers of Iroquois by the Iroquois Water Company, your Secretary visited Iroquois on March 18th, and with the representatives of the Council and of the Local Board of Health investigated the whole question, and discussed the difficulties which have been thrown in the way of the Company, and the best means of having the pipe extended to the St. Lawrence River, so that a good and safe supply of water might be insured.

The diagram herewith submitted exactly represents the position of the river, the old and the new canals, and the waterworks, and also shows the alternate proposals for extending the water pipe into the clear river water.

At a meeting presided over by Dr. Stevenson, the Reeve, at which your Secretary met the members of the Local Board of Health and several members of the Village Council, the necessity for prompt action was pointed out, the main facts of the case being,

1st. That the water pipe of the public service has for some eight months had its intake in the canal, close to the present pumping house.

2nd. That the canal water as seen by the analysis, when it was covered with ice and was receiving no surface wash, showed an abnormal excess of organic matter doubtless from the shores and bottom.

3rd. That with the onset of Spring the canal has become a reservoir for the surface wash of the country along its route for several miles from Cardinal to Iroquois, and is polluted also by whatever local sewage flows in at Cardinal, and the very notable amount of wastes from the large starch works at that place.

4th. That the water was excessively filthy with mud at the time of the visit of your Secretary, and was beginning to be affected by the pollution incidental to the presence of hundreds of men and teams along the canal banks.

5th. That to this menacing pollution will shortly be added the effects of the mud stirred up by the wheels and screws of steamers going through the canal.

6th. That as the waters grow warm, the pollution will cause bacterial life to multiply rapidly, and should disease germs be present in such filthy water, there will inevitably be a serious outbreak of disease resulting therefrom amongst the users of the canal water.

7th. That the Water Company has, by the terms of its contract, to supply the village with a pure water for domestic purposes.

8th. That the works were established in 1885, without the plans being submitted to the Provincial Board of Health; and further, that the alteration in the source of supply made last year, of which the Provincial Board should have been notified,—in accordance with the Amendments of 1895 to the Public Health Act,—was not referred for approval.

9th. That the Local Board of Health of Iroquois has passed the following resolution, requesting the Village Council to take such action as will insure a safe public water supply.

“Moved by A. E. Averell, seconded by W. J. Marsh, that owing to the impure condition of the water supplied to Iroquois, by the Iroquois Water Co., the Council of Iroquois be requested to take the necessary steps for procuring a supply of pure water from the said Company as soon as possible, and that the Secretary forward a copy of this motion to the Council Board.”

In view of the statements above recited, it is in the opinion of your Secretary urgent,

1st. That the Village Council, of the Village of Iroquois, take such steps as shall cause at once the extension of the intake pipe to the pure waters of the St. Lawrence.

2nd. That in view of this urgency, the Local Board of Health of the Village of Iroquois be instructed to at once give formal notice, based upon this report, to the Water Company, requiring it to abate nuisances and remove unsanitary conditions, as the Board is empowered to do under the Public Health Act,—being Cap. 248, R.S.O. 1897,—and to supply, within a definite, reasonable period, the village with a safe public water supply as required under the Act.

3rd. That the Local Board of Health be notified, in case action is not taken by it to have this danger to the public health removed within a reasonable period, that your Secretary be instructed to have such legal steps taken under the Public Health Act to have the unsanitary conditions above referred to removed, as may be found necessary in the public interests.

In conclusion your Secretary would suggest that a copy of this report if adopted be filed with the Minister of the Department, one copy be forwarded to the Village Council of Iroquois, one to the Local Board of Health of Iroquois, and one to the Iroquois Water Works Company.

REPORT OF THE COMMITTEE ON SEWERAGE OF THE PROVINCIAL
BOARD OF HEALTH ON THE POLLUTION OF THE RIVER AVON
BY THE SEWAGE OF THE CITY OF STRATFORD,
WITH SUPPLEMENTARY REPORT.

Ottawa, Sept. 28th, 1898.

To the Chairman and Members of the Provincial Board of Health :

GENTLEMEN,—Your Special Committee appointed to investigate the pollution of the River Avon by the Stratford sewage begs leave to report that they visited Stratford on Sept. 16th and held an investigation enquiring into the matter, taking the sworn evidence of all parties appearing before them as witnesses by complainants for the Township of Downie, and also the evidence of the City Engineer of Stratford, who was called by your committee. The evidence of the City Medical Health Officer was also taken. The City of Stratford brought no evidence to show that the stream was not polluted, while the minutes of the meetings of the Township Local Board of Health for the eleven years past were put in as evidence to show that not only had the township health authorities protested against the continual pollution of the stream, but also that the Secretary of the Local Board of Health of Stratford had been present at a meeting of the Local Board of Health of Downie Township, in 1897, when a conference took place regarding the problem.

From the minutes and correspondence of the Local Board of Health of Downie Township it is clear that the protests regarding the pollution of the river have been continuous from 1887 to the present year, such correspondence being confirmed by copies of letters in the office of the Provincial Board of Health, notably that of Feb. 17th, 1898, by the Chairman and Secretary of the Downie Township Local Board of Health protesting against the extension of the City of Stratford sewers and the continued further pollution of the river, and several references in the annual reports of the Local Board of Health of Downie Township to the continued pollution by Stratford sewers of the waters of the Avon.

Further, as will be gathered from the correspondence which is found in the office of the Provincial Board of Health from Feb. 10th, 1896, to April 19th, 1898, the Provincial Board of Health is aware that the City of Stratford had asked for that Board's approval of its sewerage extension scheme, which, as will be seen by the correspondence of Feb. 13th, 1896, was given subject to the provisos found in the following resolution which appears in the minutes of the Provincial Board :—

FEBY. 13th, 1896.

The Committee on Sewerage submitted the following recommendations with regard to the proposed extension of the Stratford sewerage system. "That the construction of the proposed extension be approved, subject to the following conditions :—1st. That the main outfall sewer be changed according to the plans submitted. 2nd. That the extension of the system be on the plans proposed, one for carrying sink water, cellar water, house sewage and roof water. 3rd. That flushing tanks be a part of the system, to be placed in proper positions. 4th. That the provisions re storm water overflows into creek be approved of whenever the Engineer's report thereon shall satisfy the Board as to the efficient character of these storm overflows, the plans for which shall be submitted for approval to the Board. 5th. That the present method of disposal be permitted during the period necessary for the construction of the main line of trunk sewer to be completed during 1896. 6th. That during this period the City Council shall have decided upon some method for purification of the town sewage which shall be satisfactory to this Board, and that the construction of such filtration plant be proceeded with thereafter at the earliest possible period. 7th. That in connection with this extension a plumbing by-law to be adopted by the City Council after approval by the Provincial Board of Health."

In addition to this indirect evidence which is in the hands of your committee, there is the large mass of direct evidence herewith submitted by the residents along the Avon and others who have known it for years to show that the stream is a polluted stream.

With regard to the sources of pollution, the complainants produced witnesses to show that the County of Perth Court House and Gaol, the Collegiate Institute, the woollen mills of E. F. Dutton, were all directly polluting the River Avon by sewers carried from them

to the stream. The statements of the witnesses will be found in the evidence hereto attached. Further, the evidence of W. F. VanBuskirk, City Engineer, of Stratford, shows that during the past eight or nine years some 5 or 6 miles of new sewers, designed for sanitary sewers, have been constructed, though as yet used largely for cellar drainage. Further, that there is no available evidence to show that such are not used for draining privies and sink water, while there has been a gradual increase of house sewers. Further, the Engineer states that the G. T. R. shops discharge water into a tile drain emptying on St. Patrick Street by an old box drain into Romeo creek. Whether or not sewage enters the drain, it discharges as dirty water into the creek. He further stated that he was aware of sewers constructed by the city emptying into Romeo or Shakespeare Creeks, as that on Gore Street and St. David Street. In answer to further questions he stated that redress for Downie Township would mean not only the construction of sewage disposal works, but also enforcing connection between house and sewer of house drain now emptying into creeks.

From the correspondence and from the evidence of witnesses forming a part of this report, it is plain to your committee that the sewage from the City of Stratford, whether from the city sewers, the county buildings, the Collegiate Institute, Dufton's mills, or from private houses is discharged into the River Avon either directly or indirectly; and that, while there was no evidence produced to show that disease had been traced directly to this pollution, there is evidence which shows that cattle pasturing along the stream drink polluted water, which from inferences based upon the experience of those engaged in cheese-making, your committee believes must affect injuriously the quality of the milk products from such cattle.

To sum up the results of the investigation your Committee would say :

1st. That the report of the Committee of the Provincial Board of Health, dated June 8th, 1886, points out that taking the estimated consumption of water of the city of Stratford at 250,000 gallons, and calculating the flow of the Avon at between 5,000,000 and 6,000,000 gallons the sewage would form about 5 per cent. of the total flow. Evidence submitted shows that the consumption of water in August, 1898, was 659,596 gallons daily. Said report which was adopted points out that the pouring of sewage into the Avon must be considered as but temporary, and that the city must be prepared to erect purification works whenever called upon by the Provincial Board of Health to do so.

2. That the evidence from the minutes of the Local Board of Health of Downie Township from October 1st, 1887, to February 15th, 1896, shows that the pollution of the Avon has been recognized as an evil which existed and which would increase naturally.

3rd. That the correspondence and minutes of the Provincial Board of Health show that for the past several years the necessity for purification of the sewage of the city of Stratford had been realized by it, and that it had laid down as a condition of the sewer extensions by the city that satisfactory sewage disposal works were to be determined upon by the City Council and submitted to it by the end of 1896, and that the Provincial Board of Health did in August, 1897, approve of the Engineer's scheme for sewage disposal by precipitation and filtration, and that the plans and details of such a scheme as modified by the engineer were submitted to the Provincial Board on April 19th, 1898, and after examination were finally approved of.

4th. That the sworn evidence of the City Engineer shows that such plans, while under consideration by the City Council of Stratford, have not been finally adopted, and that before such works can proceed the plans must be adopted by the Council and a money by-law voted upon by the people.

5th. That in the opinion of your Committee the Provincial Board of Health should intimate to the Council of the City of Stratford that, as provided under section 30, chapter 248, R. S. O., 1897, the Provincial Board does require in the interests of the public health, and notably those of the residents of Downie Township, the disposal of the sewage of the City of Stratford by sewage purification works, by such plans as have

been submitted to and approved by it, and that there seems no valid reason for delay on the part of the City Council, or any unreasonableness on the part of any person or persons, or municipality affected by the pollution by sewage of the river Avon, in seeking such legal remedy as is provided under the Public Health Act in Section 73, Cap. 248, R. S. O., 1897, for removing the unsanitary conditions created.

All of which is respectfully submitted,

(Signed). J. D. MACDONALD, }
P. H. BRYCE, } Committee.
E. E. KITCHEN. }

Supplementary Report of the Committee of the Provincial Board of Health on the Pollution of the River Avon by the Sewage of the City of Stratford.

Nov. 30th, 1898.

MR. CHAIRMAN AND GENTLEMEN,—Your Special Committee begs to submit a brief Supplementary Report in addition to the Report adopted by the Board on September 27th, 1898, re the pollution of the River Avon by the sewage of the City of Stratford.

The report of the Board's Committee then adopted contained five distinct conclusions based upon the evidence, each of which went to show pollution of the River Avon by the sewage of the City of Stratford. The Committee did not deem it necessary to mention specific instances of pollution in its conclusions, such as those of the County Buildings, the Collegiate Institute, or Dufton's Woollen Mills, since they all pollute the Avon within the corporation limits, and on page 3 of the Report are shown to be sources of pollution.

Inasmuch, however, as in the application made by the Downie Township Local Board of Health, these latter, as special sources of pollution, are asked to be investigated; and whereas it has been brought to the attention of your Board by the Solicitor for the Local Board of Health of Downie Township, that the recommendation of your Committee contained in its fifth conclusion is that your Board do instruct the City Council of Stratford to provide sewage disposal works, as your Board is empowered to do under section 30, sub-sec. 4, Cap. 248, R. S. O., 1897; and whereas it is the desire of the Local Board of Health of the Township of Downie, as stated in the correspondence, to make application to the High Court, as provided under section. 73, cap. 248, R. S. O., 1897 :—

Therefore, your Committee would recommend that the conclusions contained in the Report adopted by your Board September 27th, 1898, be supplemented by the following as section sixth :

6th. Your Committee does, therefore, advise that the Provincial Board of Health do recommend the removal or abatement of the nuisances or things hereinbefore referred to, to wit :—the pollution of the River Avon by the Corporation of the City of Stratford, the pollution of the River Avon by those responsible for sewage pollution from the County Buildings, from the Collegiate Institute, and from Dufton's Woollen Mills.

All of which is respectfully submitted. .

J. D. MACDONALD,
PETER H. BRYOE,
E. E. KITCHEN.

MINUTES OF EVIDENCE TAKEN BY A COMMITTEE OF THE PROVINCIAL
BOARD OF HEALTH RE. THE POLLUTION OF THE RIVER AVON,

By the Secretary of the Committee.

Stratford, Sept. 16th, 1898.

The committee met at 2 p.m., when Dr. McDonald, chairman of the Provincial Board of Health, presented the reasons for holding the investigation.

Ex-Judge Woods for the township of Downie presented the reasons why the township authorities have made the demands for an investigation. He presented the township's efforts since 1886 to have the matter dealt with.

The map of the city was shown, Romeo Ward Creek being presented as a chief source of complaint.

R. R. LANG, City Clerk, (sworn):

Q.—Have you any documents in your possession in connection with these matters? A.—I have in my possession the minutes of the Council from the beginning, but the other documents, except several from Dr. P. H. Bryce, have been destroyed.

Q.—Is there anything in the minutes of April 3rd, 1897, or thereabouts regarding communication with the Local Board of Health of Downie Township? A.—A communication had been sent by the Downie Board of Health, but no minute of any action taken by the Council is found in the minutes.

Q.—Do you remember a meeting of the Downie Local Board of Health in October, 1897, at which you gave evidence? A.—Mr. Galbraith was sent to inspect the proposed system. He approved of the proposed system, but as yet no change had taken place since 1884. Think the shoddy and woollen mill has a good deal to do with the discoloring of the water. The mill referred to is Duffton's mill. I have no doubt the evidence is correct, although I have no recollection of the incident.

(Signed) R. R. LANG.

Mr. Wood presented a map showing the course of the river.

MR. W. DAVIDSON, County Clerk, (sworn):

Q.—When was the Court House built? A.—The Court House was commenced in May, 1885, completed in 1887.

Q.—Are there closets and urinals in the building? A.—Yes.

Q.—Do they drain into the Avon without any attempt at precipitation of the sewage? A.—Yes; and until a month or so ago we had no complaints regarding such pollution.

Q.—Is the communication dated August 1st, 1898, the complaint referred to? A.—Yes: although there is another subsequent notice which the solicitor, Mr. MacPherson, has.

Q.—Does the House of Refuge empty its sewage directly into the Avon? A.—No; it does empty into the city sewer.

Q.—Do you know where the city sewer empties? A.—It empties into a small stream which empties into the Avon.

Q.—Is there any process of purification before it empties into the stream? A.—None, except exposure to the air a few rods.

Q.—The stream into which the sewer empties is within the limits of the City of Stratford? A.—Yes, but enters the Avon some distance from the township. This stream is not always running above the sewer, but is below.

By Mr. McPherson:

Q.—What is the difference between where the Court House drain empties into the river and the limits of the Township of Downie? A.—I would say about a mile and a quarter, it being a circuitous course.

Q.—Would you say that in your opinion the fact of there being closets in the Court House would create a nuisance in the Township of Downie? A.—No; I would think not at ordinary times, although during the court there are many more persons using the building.

By the Chairman:

Q.—How many? A.—Seventy jurors say for four days during four jury courts. The other courts are in session in December and June, the division courts monthly.

Q.—How many years were you mayor of Stratford since 1887? A.—Two years. I may further state that the sewer goes directly to the river as the County Council has been waiting for the construction of the city sewer, otherwise we would have put in a cesspool.

(Signed) WM. DAVIDSON.

ALEX. W. FISHER, (sworn):

Q.—What is your occupation? A.—Reporter on the *Stratford Beacon*, and have with me which I produce copy of the *Stratford Beacon* of January 31st, 1887. Mr. Fisher read from the inaugural address of the mayor, Mr. C. I. Macgregor, in which the mayor referred to the subject of sewerage, that nothing had been done toward the construction of the main sewer, now that the county buildings are near completion, his idea being that the main sewer empty into the Avon near the cemetery.

Extract was read from the minutes of the City Council dated April 8th, 1887, stating that the Local Board of Health of Downie protested against the carrying of the city sewage into the Avon.

(Signed) A. W. FISHER.

PETER SMITH, Secretary Downie Local Board of Health, (sworn):

Q.—What is your occupation? A.—I have been secretary of the Local Board of Health of Downie Township since 1885, when the Board was first organized.

Q.—How long have you resided in the Township of Downie? A.—I have resided in the township since 1867, some two and one-half miles from the river.

Q.—Have you any records of the Board relating to the pollution of the Avon? A.—Yes, minutes of meeting of March 30th, 1887, referring to Mayor Macgregor's address where it is proposed to empty the sewage of Stratford into the River Avon. After the subject was discussed the secretary was instructed to send to the mayor and aldermen, and a copy to the "*Beacon*" and "*Times*," notice that the Board will consider such action detrimental to the health of the inhabitants of the Township of Downie, and would strongly urge upon the City Council to adopt some other plan, as this Board will resist any attempt of such plan of sewerage.

Q.—Are there minutes of other meetings dealing with the matter, and if so can you supply the Committee with copies? A.—Yes; I shall do so, and with the following:—

Oct 1st, 1887.

March 3rd, 1888, (extract from report to Provincial Board of Health,) adopted by the Local Board of Health.

Sept. 28th, 1889 (extract from report to Provincial Board of Health,) adopted by Local Board of Health.

Oct. 29th, 1892 (extract from report to Provincial Board of Health).

March 16th, 1895 Minutes. These minutes were communicated to the City Council.

Feb'y 15th, 1895. The matter was discussed and a letter was sent to the Provincial Board of Health.

Q.—Have you received any communication from the City Council acknowledging receipt of communications? A.—None.

Q.—Did you cause the city to be notified this year, 1898, to discontinue? A.—Yes, through Mr. Mabey, solicitor, who was instructed by the Board at a meeting held on June 25th, 1898.

Q.—Did you receive notice to produce witnesses before Dr. P. H. Bryce in a letter from P. H. Bryce, dated Sept. 12th, 1898? A.—Yes.

Q.—Did you receive letter, submitted by you, from R. R. Lang, City Clerk, dated Sept. 7th, 1898? A.—Yes, this is the first and only communication from the city authorities to the township authorities in reply to their several communications. I have not replied to it and the township authorities have held no meeting with the city authorities with regard to the matter. No answer was sent as I received the notice from Dr. P. H. Bryce, dated Sept. 12th, before any action could be taken.

By Mr. McPherson:

Q.—You cannot say personally that you know of the pollution of the river, or of anyone's health being prejudicially affected by the state of the river. A.—I cannot give evidence of such pollution or of anyone injuriously affected.

Q.—Who was Chairman of the Board of Health in 1885 and 1886. A.—Mr. Lang

Q.—Was Mr. Fram a member in 1887? A.—Yes.

By Mr. McPherson :

Q.—Have you ever complained to the County Council regarding the connection between the County Building and the river before August, 1893? A.—Not to my knowledge.

By Mr. Woods :

Q.—Was there three or four years ago an outbreak of typhoid and diphtheria in the township? A.—Yes.

By Mr. Woods :

Q.—Do you know that such was not due to the pollution of the river? A.—I could not say whether it was or not.

Q.—Do you know Wm. Woods in Downie Township? A.—Yes.

Q.—Were there cases of typhoid in Mr. Woods' family at that time—whose place is near the river? A.—Yes, I knew of one case.

Q.—How far is Mr. Woods below the city? A.—It is on lot 10, con. 5, or 4 or 5 miles around by road.

Q.—How near is the house to the cheese factory and piggery? A.—About 45 rods, and about the same from the piggery.

Q.—Is this cheese factory and piggery one which has been referred to in reports to the Provincial Board of Health? A.—Yes.

(Signed) PETER SMITH.

R. H. PACKHAM, (sworn):

I reside on lot 4, concession 2, adjoining the city corporation.

Q.—How long have you resided there? A.—For three years past.

Q.—Does the river run near your farm? A.—Yes, within 25 rods of the house.

Q.—Are there many in your family? A.—Only my wife and myself.

Q.—How long have you known the river near where you reside? A.—About 15 years.

Q.—Can you say there is any difference in the appearance of the stream since you have known it? A.—I do not think it as clear as when I went there three years ago.

Q.—What difference have you noted? A.—It is often bad-smelling, muddy looking, and with a scum on it; sometimes it is black.

Q.—Do you know what this is due to? A.—I believe it due to the sewage and the woollen mill.

Q.—Will your cattle drink the water? A.—Yes, if they cannot get better, but they prefer well or spring water.

Q.—Are there growths along the shore that used not to be there? There is a slimeiness along the shore and abundance of weeds.

Q.—Is this a slow running stream? A.—When low it is slow, not more than 6 inches deep, and at one place not more than 5 feet wide. This is on my farm.

Q.—How far do you live from the nearest sewer outlet? A.—A little over 100 rods.

Q.—Do you live near the island on your farm? A.—About 30 rods. The river is narrowest at the island on my side, but the stream is wider on the west side of the island.

Q.—Do you use water from the river? A.—No.

Q.—Where is your well? A.—It is higher than the river and has a depth of 25 feet.

Q.—Have you ever smelled bad smells at the house? A.—No; but if you go near the river in the evening in summer there is a bad smell.

Q.—Have you had any sickness which you attributed to the river? A.—I cannot say that any of my family have been injuriously affected from the river.

Q.—Are you in the dairy business? A.—No, and do not use the water from the river.

By Mr. Woods :

Q.—Is the outlet of the sewer spoken of by Mr. Davidson, on the lot next yours into a living stream? A.—No; I have seen it running quite freely in spring, but pretty well dried up in summer.

By Mr. McPherson :

Q.—Have you known typhoid or diphtheria near you? A.—No, but some cases further down the stream. I have springs on my place, but if I had not I would not like to use the milk from cows drinking the river water.

(Signed) R. H. PACKHAM.

WILLIAM WOOD, (sworn) :

I am a farmer residing in Downie Township.

Q.—Where is your house? A.—It is above the cheese factory. I have lived there 59 years. The Avon was known as a trout stream with lots of fish. I used to drink of it often as it was clean then. Now it is dirty, has dirt accumulating on top of it, which looks like a thick seum. This is wherever there is an obstruction, and if stirred up there is a terrible smell. It is worse in low water in summer, but is not as bad since the rains came. The river water rises and falls daily.

Q.—Have you springs? A.—No; I have to use the river water for the cattle as I have no springs. Where the water is stirred up the smell is like a privy. The horses seem to dislike the water.

Q.—Have you ever had typhoid in your family? A.—One of my girls came home with it from the neighbors who lived on a farm not far away where there were other cases.

Q.—Have you had sickness directly attributable to river water? A.—No.

Q.—Do you supply the cheese factory with milk? A.—At times.

Q.—Do the cattle stand in the stream? A.—Yes, much in hot weather and fly time.

Q.—Do their udders become soiled? A.—I have not noticed it specially.

Q.—Do you think it good water for the cattle to drink? A.—No, not from the amount of filth present.

Q.—How long since you drank water out of the river? A.—Not since I went to school.

Q.—What was the river like in 1885? A.—Very different from what it is now.

(Signed) WILLIAM WOOD.

H. A. SOUTHWICK, (sworn) :

I am a cheese-maker and proprietor employed in making cheese at the factory lot 11, con. 6, in Downie Township.

Q.—How long have you been there? A.—Since 1885.

Q.—Is the river clear above the factory? A.—No, it has been in bad condition this summer for cattle to drink. It is oily looking, at other times green, at other times contains lumps of matter which would stop behind any obstruction. This is the case as it comes over a gravelly bottom past the factory. The water is about 5 feet wide at this point and 8 inches deep. The factory is about thirty feet from the river. I have not noticed smells from the river while in the factory. I get milk from farmers whose cattle drink the river water. Some of them are on farms nearer the city than is the factory. The factory is six miles from the city. Much whey is sent home in cans. There is a pig pen some 350 feet from the factory and 30 feet from the stream. We keep 50 pigs. The drainage is not from the pens into the river.

Q.—Has your experience been that the milk from cows which drink or come in contact with such polluted water as that described by you in the river Avon is affected unfavorably? A.—Yes, my experience is that milk from such cows takes on a bad flavor. I have sent home milk with such bad flavor coming from such cows.

Q.—Have you a large family? A.—Four of a family and two men. We have had no sickness for several years past.

Q.—Have you noticed during the fifteen years an increased pollution of the river? A.—It has been more polluted this spring than I ever saw it before.

Q.—(By Mr. McPherson). Who was it whose milk was returned? A.—I am not prepared to say. At least one person's milk.

Q.—Do you know of anyone's health being affected by the polluted milk? A.—No.

(Signed) H. A. SOUTHWICK.

THOMAS DUNN, (sworn):

I am a farmer and reside on lot 5. con. 2, Downie Township, adjoining the corporation of Stratford. The river Avon runs through the south-east corner of my farm. I have lived on the farm for 52 years. It was then a clear trout stream fit for drinking purposes. Now it is filthy. I see no fish except in spring. I attribute the state of the river to the filth of the town of Stratford. Am about a mile and a half below the town. The appearance of the river when filthy is a green scum all over it, as in hot dry weather. It smells badly at times. The scum was not on the river years ago. The water on the stream above Stratford is not the same as it appears on my farm. My cattle drink and stand in the river. I have never noticed any difference in the milk since the cows go to the stream. I think, however, that the stock have not thrived as well. Last year I found a two-year old dead on the bank of the stream. I do not know what caused its death.

Q.—How many cattle have you? A.—Some 22. Have springs, and two wells and troughs. About one-half the cattle shut back and have access only to the river. These are the young cattle. Q.—How far is your home from the river? A.—About 40 rods. I have noticed a fog rising from the river some nights, producing a disagreeable smell.

Q.—(By Mr. McPherson). Have you known anyone's health to be affected by the river? A.—No. A few of my cattle were sick last summer (1897). We kept them in gave them a little medicine, and kept them from the river water till they were better.

(Signed) THOMAS DUNN.

R. A. BALLANTYNE, (sworn):

Am a tenant on the farm, lot 10, con. 4, Downie Township, the next farm on comes near the cheese factory. The river runs through the farm. Do not live there. I do not consider the river water fit for cows to drink. There is a scum on the water where it is still; a greenish growth. My horses won't drink it. The stream is about 20 or 30 feet wide and one or more feet deep above the cheese factory.

Q.—(By Mr. McPherson). Have you heard of anyone's health suffering from the water? A.—No, but know of no one ever drinking the water. I have bathed in the river once this summer, but it was not very clear or very deep.

(Signed) R. I. BALLANTYNE.

STRATFORD, Sept. 17th, 1898.

The Committee met at 10 a.m. in the Court House.

DR. J. A. ROBERTSON, Medical Health Officer, of Stratford, (sworn):

Have been Medical health Officer for eight or ten years. Did in June last make report to the Local Board of Health on the matter of the sewage disposal, urging that the Council adopt some suitable means of treating the town sewage. I am not aware that the Board has received any reply from the City Council. The total houses in the city are probably 1,500 at least. There has been public water since 1885. There are 150 to 200 water takers.

Q.—What is the number of water closets? A.—I am not aware how many water closets are established in the town.

Q.—Can you tell the Committee how the house sewage is disposed of? A. House drains which carry sewage and all house slops empty in some cases into the town sewers, and in others into the open ditches along the street, also into Romeo Creek. All of the creeks and drains lead to the Avon. Romeo Creek has been from time to time deepened, principally to prevent weeds and to make a better outlet for cellar drains. The same deepening has been made use of by some householders for receiving sewers from houses with water closets and house sinks.

Q.—(By Mr. Wood). Do you know the creek near the Collegiate Institute? A.—Yes, I have noticed smells along it in the evening.

Q.—Do you think Romeo Creek from Erie St. to the outlet in a sanitary condition? A.—No, as it is used as the outlet for privies, and house drains.

(Signed) J. A. ROBERTSON.

ROBERT PEARSON, (sworn) :

Have been caretaker of the Collegiate Institute for 10 years.

Q.—You live in the building with your family ? A.—Yes.

Q.—You know the creek near by ? A.—Yes.

Q.—Is the neighborhood savory or unsavory ? A.—It is very bad smelling at times.

Q.—How many pupils and teachers are there ? A.—200 pupils, and 7 teachers.

Q.—How many members in your family ? A.—There are 8.

Q.—When was the method of disposal of the sewage of the building changed ? A.—About 2 years ago. Before that there were outside closets. When these were done away with closets were put in and a drain laid from them to the river.

Q.—About what is the distance ? A.—About 300 feet.

Q.—Do you know of any obstacle why proper receiving tanks should not be put in and the sewage purified ? A.—No.

Q.—Do the house sinks connect with the closet drain ? A.—No, they are laid to the river by separate drain.

By Mr. McPherson :

Q.—Does the bad smell arise from Romeo creek or from the river ? A.—It arises from the creek on the south-west side, the collegiate drain enters the river about 50 feet from the mouth of the creek.

(Signed) R. H. PEARSON.

THOMAS WOOD, (sworn) :

I am a farmer and live on lot 13, con. 5, Downie Township. I live just below the cheese factory, about one farm below Mr. Wood's farm. There is no noticeable difference between the river at his place and mine. The river at my place is different at different times of the year. In July and August when the water is low there is a dirty green scum at any eddy or obstruction. A greyish substance sticks on the stones when the river is low. Rain water takes this away. There is a smell in the evening at times, and there is often a disagreeable smell in the morning. I was born on the farm. The stream used to be a clear trout stream. I have gone fishing and seen two-thirds of a patent pail of trout caught. There are no trout now, and I do not think they would like the stream.

Q.—Do your cattle use the stream for drinking ? A.—They usually go to the spring trough, although I have seen them drink out of the river. I do not think the water healthful for the cattle. They stand in the stream in hot weather. I was talking with a ferrier about my cattle with sore eyes. I think the flies cause the sores, and then the cattle in the stream splashing the water on the sores tends to make matters worse. The veterinary surgeon thought this would tend to make them in the state they were. I do not send milk to cheese factory. I am not aware of any sickness in persons I know of as due to the stream.

(Signed) THOMAS WOOD.

JOHN PETHICK, (sworn) :

I live on lot 3, con. 3, Township of Downie. I have lived on the place during the last 20 years, and have been in the township since a boy. I have known the stream since a boy, and it was then as clear as any stream I ever saw. I know it was a trout stream at one time. The river water this summer has been in a filthy state. At times with a width of a rod or more you could not see the water for the filth on the surface. I have seen it worse in places where the river is sluggish.

Q.—How is the river at Hoontin ? A.—I do not know. The school I attended was near where the cheese factory now is. The river does not look so bad now that the rains have washed the stream out. When the mass which collects gets going with the wind it goes down the stream in lumps. I have taken a pole and broke up a mass and found a stinking smell like a closet. This is worse on some days than others. Worse on a dull, foggy morning.

Q.—Where is your house ? A.—My house is 40 rods or so from the stream and we notice the smells coming up from the river at times as far as the house. It is the same smell as down at the river. My cattle will not use the river water. I send milk to the factory.

By Dr. Kitchen :

Q.—Have you known of milk being returned on account of this stream? A.—No; but I do know that milk has been brought home by my boy who drives, as not being fit for making cheese. The land along the river valley is all pasture land, and considered the best by all the farmers.

Q.—Do you know of any sickness caused by the river water? A.—I cannot say that any sickness in my house or neighborhood has been caused by the river.

Q.—Who is your neighbor? A.—Forbes Edmunds.

Q.—Do you know that he had two cases of typhoid fever several years ago? A.—Yes, but I do not know the cause.

(Signed) JOHN PETHICK.

WILLIAM CLAWSTON, (sworn):

I live on lot 7, con. 3, of Downie. I have lived on the said lot since I was born. Am next up the stream from Mr. Pethick.

Q.—You heard Mr. Pethick's evidence as to the stream? A.—Yes; I agree with him, but I think it worse than he made it. The grey matter is like he described it. I have not noticed any oily stuff at Dunn's bridge. The river is dirtier than it ought to be.

Q.—Do your cattle drink the water? A.—I do not think the water good for cattle. My cattle do not like to drink it, though they have to drink it as I have little else. The water now is much worse than it was ten years ago. It is getting worse all the time. It often has an offensive smell, bad when stirred up. I have smelled it as far as the house occasionally. We live 40 or 45 rods away. The grey matter is like refuse from water closets cleaned out.

By Mr. McPherson :

Q.—You are in sight of Dunn's bridge? A.—Yes.

Q.—You have seen boys bathing there often in warm weather this summer? A.—I bathed once this summer in the river when it was clearer than usual, but it was not fit for use. Our cistern was dry.

(Signed) WILLIAM CLAWSTON.

GEORGE FRAME, (sworn):

I am a farmer and reside on lot 15, con. 4, Dowie Township. I am now member of the Local Board of Health of Downie, and was member of the County Council in 1887. I was not a consenting party to the sewage from the county buildings going into the Avon, and stood for earth closets at the time, as the people down the river were complaining of sewage in the river. I have always been interested in the state of the river. I saw it two days ago just outside the boundary of the city for half a mile, and it ran along like whey and not like water at all. At Dunn's bridge I see it occasionally and it does not appear well. I do not think the water fit for anything, much less to drink. I know there has been since 1885 an objection to the pollution of the stream by the farmers of Downie.

(Signed) GEORGE FRAME.

GEORGE WOOD, Reeve of Downie, (sworn):

I am chairman of the Local Board of Health in the place of Mr. Lang, who has retired from ill health. This is my second year as reeve. Was in the council before. There were protests to the city for years against the pollution of the river. I do not live on the river, but see it occasionally. When I have seen it in July and August it looked bad. I would not like to have the water used, and would not like a farm on the river, for it is of no use to a man, it is an injury. I am not sure of any cases of contagious diseases occurring along the river which the Board had to deal with, except one case this summer, but do not know the cause.

(Signed) GEORGE WOOD.

JAMES CLYNE, (sworn):

I reside in the Gore of Downie. Have been member of the Local Board of Health since 1885, since organized. Have had to do with school water, cheese factories, and pollution of the Avon. I know that protests against the pollution of the river have been continuous for years. General complaints have been made against this pollution. Twenty years ago it was a clear, fine stream; for ten years it has been a polluted, dirty stream. I have recently seen it above the city and it is as clear as it once was below. I know good water, as I live on a clear spring creek.

By Mr. Smith :

Q.—How long since the stream was in a filthy state ? A.—Have noticed that during the last fifteen years it has been getting worse.

Q.—Is it worse in low water ? A.—Yes.

Q.—Do you know the cause ? A.—Yes ; I think the sewage from the City of Stratford explains it.

Q.—Have you seen it often ? A.—Yes, occasionally.

Q.—You base your evidence on the casual observation of the river ? A.—Yes, from the materials I have seen in the river in the city, I think its condition is explained.

(Signed) JAMES CLYNE.

THOMAS STEELE, (sworn) :

I live on lot 21, con. 10, of Downie. I am a member of the Local Board of Health, have been for three years.

Q.—You are aware of the complaints regarding the river ? A.—Yes ; I have therefore given the matter attention. I have frequent occasions for observing the river and have seen it at different points at different seasons of the year. In general terms I would say that the water of the stream where I reside will compare favorably with other streams. There is more than 10 miles of river from Stratford at Avonton. I never could notice pollution, but there was complaint made to me of smell at that point. Farther up the nearer you get to Stratford the river is more polluted. 3 weeks ago I went by Dunn's Bridge to inspect the river. Its appearance was very bad. Mass of solids in the running water. This cakes in stagnant water. You could not see the water under the scum. The smell was bad. I remember crossing between the cemetery and the hospital some three years ago. I saw a similar collection on the water and the water was dark and oily. In fact the nearer you came to the city the greater seems the pollution, and as the last witness stated the farther you get above the city the clearer the river gets.

Q.—(By Mr. Smith). Is there not a mill in Stratford which pours much inky matter into the sewer ? A.—Yes ; but I do not think this accounts for the solid matter floating on top.

(Signed) THOMAS STEELE.

The minutes of the Local Board of Health of Downie were handed to the Provincial Board of Health for reference.

W. F. VANBUSKIRK, C. E. (sworn) :

At the request of the Committee of the Provincial Board of Health said :

Have been City Engineer of Stratford for one year, but have lived in Stratford for about three years and have done occasional engineering work during the last three years for the city. My duties include all new work, its design and construction, and general adviser to the Council. There are some 5 or 6 miles probably of new sewers constructed within the last 8 or 9 years, designed for sanitary sewers, but so far have been used principally for cellar drainage and street water. Heretofore private parties have been in the habit of connecting house cellar with sewer without permission in many cases, but in others permission to tear up road is obtained from the Street Commissioners. No records have been kept of drains put in on permits, but we do now. Cellar drains constructed latterly have been of vitrified pipe. There is no available information as to whether such tile drains are not used for draining privies and sink water. The number of water closets is small and must be because the water service is small. There are not probably more than 200 houses supplied with public water service. There has been a gradual increase of house sewers. The City Water Co. supplies water to the railways and the shops which employ some 600 hands. There are only privy vaults so far as I know at the G.T.R. workshops. A large amount of the water from the shops comes into a tile drain emptying on St. Patrick St. by an old box drain to Romeo Creek. This water is used for washing boilers they tell me, and I have an idea that there is a urinal connected with it, but I do not know for certain. It at any rate arrived in the creek as dirty water. There are several factories employing a number of hands in the city. I have no idea how many house connections have been made between water closets and sewers, but there are hotels and other buildings connected.

Q.—Is there at the present time any scheme which has been adopted by the city council for the treatment of the sewage of Stratford before allowing it to flow into the Avon ? A.—There is a scheme drawn up by me last month under instructions of the sewerage committee of

council for disposing of the city sewage. The plans were before the Provincial Board of Health, and the scheme is at present under consideration by the city council. I am not aware of any objection having been made by the Provincial Board of Health to the prosecution of the scheme.

Q.—What steps are required now for carrying out this work? A.—The adoption of the scheme by the council, and the submission of a money by-law to the people.

Q.—How long would be required to have such a by-law submitted? A.—I think it requires advertising for about a month.

Q.—Could the work proceed in winter? A.—Not very well, the greater part could not be done in winter.

Q.—(By Mr. Smith). What has been the cause of the delay in the adoption of some scheme? A.—The city's sewerage committee which has been studying the question of sewage disposal have been under the impression that there was no hurry owing to the small number of sewer connections.

Q.—(By Mr. Smith). When did you report to the council your scheme for sewage disposal? A.—About the end of June, 1898.

Q.—Do you remember a deputation appearing in February, 1896, before the Provincial Board asking permission to extend and alter the sewerage system of Stratford? A.—As I was not there I could not say positively.

Q.—Are you aware that the extension made in that year was dependent upon the council having arrived at some plan for the disposal of the sewage by the end of the year? A.—Yes, the deputation went to get permission to make changes in the outlet and others, which were proposed by me. These changes presupposed a method of disposal of sewage by gravity instead of by pumping. The council at that time was satisfied that the sewage could be disposed of on a farm, but I practically condemned the scheme as I found there was not sufficient area for precipitation at a reasonable cost, and so have advised a system of sedimentation and filtration.

Q.—Are you aware that such a scheme has been practical elsewhere? A.—Yes, and can be constructed at a reasonable cost. (In answer to Mr. Smith) The city council has not allowed the matter to drop long.

Q.—(By Mr. Maybee.) Do you know of any sewers constructed by the city emptying into Romeo or Shakespeare creek? A.—Yes, one on Gore St. built some three or four years ago. It is nearly one half mile long and empties directly into Shakespeare creek. I do not think there are many house connections because the sewer is perfectly dry sometimes in summer.

Q.—What others? A.—An old sewer on St. David St., a box drain built twenty-one years, empties into Shakespeare creek.

Q.—What others? A.—John St. sewer empties into the river. Has not very many connections for its length.

Q.—What others? A.—About all the others enter the main sewer.

Q.—Do you know of sewers from buildings emptying into these streams which could be connected with the city sewers. A.—Yes, I know of several.

The redress for Downie township would require not only sewerage disposal works then, but enforcing new sewer connection between houses and sewers instead of into creeks, and also leading some existing sewers into the trunk sewers, and also a large extension of the lateral sewers on the Macdougall plan, and the prevention of pollution by dumping garbage and refuse into the creeks and river. A.—Yes.

Q.—What would be the cost of completing the trunk sewer along the south side of Victoria Lake from the skating rink to the main outlet sewer as per plan. A.—About £2,500.00.

Q.—This money raised by by-law some two or three years ago by debentures is available for the purpose is it not? A.—Yes.

Q.—Is there any reason for this work not being done? A.—No local demand for its completion. and other work was pressing.

Q.—Would the sewer intercept the sewage now going into the pond and river? A.—Yes, such as the collegiate institute, the court house and gaol, Dufton woollen mills, and government buildings.

Q.—What buildings on Ontario St. drain into the river and pond? A.—Only the Post Office.

Q.—Do you know where the sewage of the Gordon Block goes? A.—I have not followed the pipes in the building.

Q.—You put down a sewer on Market St. last year? A.—Yes, but the only connection with that from the Gordon Block was one under Mr. Hardy's store.

Q.—Do you claim that all private water consumers have water closets? A.—I do not know.

Q.—Some of these water consumers use cess pits? A.—Yes.

(Signed) W. F. VANBUSKIRK.

Mr. Mabce submitted table of pumping of water works as follows :—

June, 1898.....	605,838 gallons.
July, 1898.....	662,829 gallons.
August, 1898.....	659,596 gallons.

Mr. Judge Woods further said :—Dealing with the main sewer will by no means remove the evil. The township has tried twelve years to get redress and could not. We hope that the report will bring home to the people that the township has striven in vain.

Mr. VanBuskirk presented the committee with a copy of the city map.

The above evidence concluded the investigation.

REPORT RE PORT DALHOUSIE DRAINAGE NUISANCE.

By the Secretary.

TORONTO, June 29th. 1898.

To Dr. Considine, Medical Health Officer, Port Dalhousie, Ont.

DEAR DOCTOR,—In compliance with the request contained in your letter of the 8th inst. I beg to report that I visited the Village of Port Dalhousie on June 22nd., and in company with yourself, the Reeve and several other interested parties examined the several places complained of as nuisances from local drainage. In both instances I found the complaints borne out by facts, and see no way of an effective and permanent remedy except by the construction of two drains under the local improvement clauses of the Municipal Act, being sections 668 and 669 of chapter 223, R. S. O. 1897. The Public Health Act directs that the Local Board of Health abate nuisances, and this is the ready way of having the work done and the cost assessed.

I would therefore advise that,

1st. A 6" glazed tile sewer be laid along Main Street at such a level as will be out of danger of frost, and so that a flush may be readily be supplied to it, in the absence of regular water works, from the canal basin.

This work must be done by the corporation, leaving an offset for house drainage to each lot, and thereby the householder will be enabled to make a four-inch tile drain connection properly trapped to his premises. I forward a copy of our Model Plumbing By-Law for adoption by the Council as a Village by-law.

2nd. A similar drain should be laid down the Ravine at the back of the stores on Main St. to the canal for the drainage of the properties contiguous. In addition to the sections of the Municipal Act already quoted, I refer you to section 673 expressly dealing with the distribution of cost of local improvements.

I further advise the Council to employ some engineer accustomed to dealing with the local assessment of land drainage, both to make a plan and supervise the construction of these sewers as well as to report on the properties to be assessed.

I shall be pleased to learn that the beginning has been made of a sewerage system for the town, which with a little energy might be made cleanly and attractive for many summer visitors and healthful for its own inhabitants.

Please lay this report before the Local Board of Health and the Village Council as soon as possible.

 REPORT *RE* LONDON PACKING COMPANY NUISANCE.

Toronto, Jan. 26th, 1898.

To the Members of the Provincial Board of Health.

GENTLEMEN,—Your committee to whom was delegated the duty of inspecting the establishment of the London Packing Co., in September last, reported at the last meeting of the Board that they had proceeded to Pottersville, London Township, and had taken evidence on September 14th 1897; and further that in view of the verbal opinions then and subsequently expressed, regarding the method of removing the cause of further complaints, and the statement made in a letter by the Manager Mr Ginge, dated Oct., 8th 1897, that he was then taking steps to carry out the Board's expressed opinion, that by an elevated tank, the effluent from the factory, might be pumped and then run by gravity to the lighter land of the field, there to be utilized as a sewage farm, your committee did not deem any more formal report necessary.

Inasmuch however, as information has been received both from the Reeve of London Township, and Mr. Shore, M. P. P., during the last month, that the company has as yet taken no action towards carrying out the proposed improvements, your committee does now beg leave to report.

1st. That it finds from personal investigation in both June and September, 1897, that the disposal of the waste effluent from the factory, was not of a satisfactory nature, and that both an aerial nuisance exists, and that the creek was notably polluted below the factory.

2nd. That the sworn statements of different witnesses further give evidence that such conditions of nuisance are more or less constant, and that the then existing modes of disposing of the effluent from the factory, were insufficient to prevent a recurrence from time to time of the nuisance.

3rd. That in the opinion of your committee, the abatement of the nuisance especially complained of, viz., the polluted waters of the creek, demands that the effluent wastes be discharged on a much larger area of land than at the present for filtration, and at a distance farther from the border of the stream.

4th. That in the opinion of your committee, the proposition contained in the letter of Mr. Ginge, the Manager, will be a simple and efficient mode of abating the nuisance, provided that the land used is kept deeply ploughed and permeable to air, and that after every discharge into furrows, the furrow be turned over the wastes by which the absorption of the gases of putrefaction will be complete.

5th. While subsoil drainage would increase the porosity of the soil and its ability to deal with the wastes, the necessity for this is a matter of detail depending upon the area of land used, and the amount of the daily sewage.

6th. That the beneficial effects of the utilization of sewage of the London Asylum, and solid refuse from the packing factory daily hauled to the Asylum gardens leave your committee no room for doubt, but that the cost of the disposal of the effluent wastes from the factory can be practically made up by the increased produce from the sewage farm.

7th. That in the opinion of your committee, the Local Board of Health will now be justified in taking action as provided under section 64 of the Public Health Act, subsection 2 in seeking an Order of the Court to compel the Canadian Packing Company to at once introduce such methods as will abate the nuisance.

All of which was respectfully submitted.

(Signed) J. D. MACDONALD,
E. E. KITCHEN,
P. H. BRYCE.

INSPECTION OF OAKVILLE SLAUGHTER HOUSE.

*By J. J. Cassidy, M.D.**Toronto, August 10th, 1898.**P. H. Bryce, Esq. M.D., Secy. Prov'l Board of Health, Toronto, Ont.*

DEAR DOCTOR,—I went to Oakville on the 6th inst. by the 2.10 p.m. train, I called upon Mr. W. S. Davis, town clerk, upon my arrival, and he accompanied me to the spot where the nuisance complained of was said to exist. (see Mr. Davis' map). The Public and High School is a large building of two stories, situated on Main street, and the rear portion of the school property runs along the bluff skirting the valley of the Twelve Mile Creek. Situated on the street and in front of this school is a well, worked by an iron pump. It is a public well. On testing it there was found to be a good supply of water. At this spot, beside the well, the disagreeable odor of pig manure was perceptible though no wind was blowing. Mr. Davis said that in damp weather the odor was much more disagreeable.

Entering a lane, which skirts the eastern side of the school enclosure for a short distance and then turns at right angles towards the west, we walked up to the slaughter house, which by measurement (estimate) is not more than 270 feet from the eastern wall of the school house. The slaughter house, which looks like an old wooden stable, is situated immediately in the rear of (about 30 feet from) Mr. Hillmer's house. Mr. Hillmer lives in this house. The slaughter house contains a killing room, a pen, and a third room which might be used for preparing and dressing meat for market. These rooms all communicate by openings. A rough wooden trough protrudes from the lower part of the frame, and was said by Mr. Davis to be used to catch blood from the killing floor. The walls of the killing room were stained with old blood. Ashes had been scattered on the floor, but the odor from the premises and the surrounding ground was of a very disagreeable character. No well was visible, and on inquiry I was told by Mrs. Hillmer that the necessary water required at the slaughter house was obtained from a well situated inside their cottage. In a pen near by were two calves. I saw no other animals intended for the market.

Accompanied by Mr. Hillmer, Sr., owner of the property complained of, I descended the steep bluff which runs at the rear of the school property and Mr. Hillmer's lot, and walked through a piece of swamp land lying at the base of the bluff along the course of the Twelve Mile Creek. Mr. Hillmer told me that he rented ten acres of this swamp and allowed hogs and cattle to roam over it. He said that offal from the slaughter house was fed to the hogs. The odors arising from this swamp were disagreeable. It occurred to me that a few drains running from the swamp into the creek near by would be of service in removing a lot of offensive vegetable and animal debris from this unsavoury locality. It may also be true that some of the odors complained of may be due to this swamp. Skirting the bluff, Mr. Hillmer and I returned to the street close to Mr. Hillmer's house which is situated on the same side of the street as the school house.

The charge against Mr. Hillmer, *i. e.*, that the slaughter house kept by him is malodorous and is not sufficiently removed from the school house, his dwelling and the street is true. Mr. Hillmer contends that the well in front of the school house is public property and can be used by him and his servants if they wish. He denies using it and showed me another good well belonging to him which was situated a short distance from the school.

Mr. W. H. Young, ex-mayor of Oakville, whom I saw afterwards, informed me that there was a second slaughter house situated in the eastern end of the town against which complaints had been made in 1897 but not so far during the present year. He said this building had originally been used as a stable. I did not inspect it.

I am, very truly yours,

(Signed) J. J. CASSIDY.

REPORT OF NUISANCES BY RAILWAY CATTLE YARDS, PIGGERIES AND SLAUGHTER HOUSES.

By the Secretary.

Toronto, August 12th, 1898.

Mr. Chairman and Members of the Provincial Board of Health :

GENTLEMEN :—By reference to the correspondence herewith submitted by your Secretary, it is apparent that the disposal of animal refuse is a subject, not only responsible for a nuisance and danger to health of a most important character, but one which, hitherto our Local Boards of Health have found themselves incapable in a large degree of dealing with. Some of the reasons for this are :—

1st. That such materials owing to their being incidental to the growth and development of our animal industries, necessarily not only exist, but tend to increase in the growth of such industries.

2nd. That they occur in manure heaps in quantities on farms, and their existence is looked upon as not only necessary, but harmless.

3rd. That being in our towns and cities looked upon as waste products, they are considered rather as a nuisance than an article of commerce.

4th. That owing to badly located cattle-yards and stables as well as defective construction, and the absence of means for systematic and effective cleaning, these materials harmless at first in themselves, are allowed to accumulate, and by decomposition allowed to become productive of most serious nuisances.

5th. The varying character as regards nuisance of the several classes of animal refuse.

By reference to the correspondence it will be seen that the materials are divided into three classes practically.

1st. Those incidental to the stock-yards, and notably hog-pens, which are used for shipping animals along our chief lines of railway. Commonly the station is in or near the village or town, and with habitations close at hand. At first there was but an occasional car shipped, but this has grown to several or many during the week. Yards are enlarged generally close to the freight stations. Often on railway property for public convenience, such are at first not a serious nuisance, since the animals are in a pen and are loaded on the car when they arrive at yard. Now, however, a number of car-loads are often collected in lots, the result being that several hundred animals are kept for from 12 hours to several days in these yards, which have now been specially constructed for them ; and hence it happens that these become littered with manure which is tramped into the ground, which is not covered over against the wet, and has added to it the refuse food which is carelessly fed the hogs in crude troughs. While care to remove regularly as much as possible this animal refuse is often seen at some cattle yards, yet at others very great indifference is shown ; and in almost every case the work of removal cannot be thorough, owing to there being no floor but the ground, no roof to protect against the water, and no water with efficient drainage to flush the floors. So as far as your Secretary is aware, no properly constructed and equipped cattle and hog-yards exist at any market or railway station in Ontario ; and the complaints are wholly dependent upon the amount of business, the location of the yards and the incident of having a soil varying from a heavy clay to the lightest sand. In some cases again, the nuisance of yards is added to by the cleaning of cars at points near dwellings. If flushed, the refuse water lies putrefying along the railway, or if drained into a creek becomes the frequent conveyor of hog cholera to the neighboring farms.

Illustrations of complaints regarding this class of nuisance will be found from Teeswater, Rodney, Walkerville, Tweed, Galt, Creemore and elsewhere.

A second and most serious class of such nuisances arises in connection with the piggeries which exist in the neighborhood of cheese factories and creameries for using the whey and milk supplied by them.

The causes of the nuisance are the same, and the nuisance is much more extended, since the hogs are kept and less care even is usually taken to give them good pens. The first class located in towns and cities, generally affects more persons directly and are more likely to be kept fairly within bounds; but the latter too often create a larger evil, affecting the commercial character of the cheese and butter products. Besides this, the old complaint of sour whey being carried from cheese factories in the very cans used to bring fresh milk to the factory seems to-day to prevail as formerly.

For instance, I visited very recently a new cheese factory, started this year, and found the whey-tank an open wooden cistern sunk in the ground and within three feet of the room where the cheese was made, the pipe leading without a trap directly from the barrel to the room, while at a distance of one hundred feet was an elevated tank with a hose attached by which the factory patron could fill his tins as he started for home.

The illustration affords food for reflection as well as supposedly first-class food for the English market.

The third, and even more common source of nuisance is that from slaughter houses. The most miserable of all structures, usually in the outskirts of a town or village, without a tight-floor or a single convenience for properly collecting blood and offal, either for boiling or removal; no drainage, no water supply for proper flushing; these sources of the meat foods of our people, abound almost everywhere, and the horror is added to by the almost universal feeding of raw and decomposing offal to the hogs, which is to be turned into pork. The persistent and continued existence of this evil we speak of, legislation regarding which has been placed on the Statute books for the use of Local Board of Health, is not more a commentary upon the wholly inadequate basis upon which Local Boards are established and carry on their work, than upon the indifference of the public who patiently endure such a condition of affairs.

I shall refer to but one instance illustrated in the correspondence from Oakville.

May 19th.—A complaint received regarding nuisance caused by slaughter-houses and piggeries near the schools.

May 20th.—Clerk notified and asked to explain by diagram their location and whether licensed, and how refuse was disposed of.

May 25th.—Clerk makes reply. States slaughter-house is on bank of creek; refuse fed to hogs; nothing but natural drainage; no licenses issued. Diagram shows pens some 150 to 300 feet from school house.

May 26th.—Reply sent to Local Board pointing out that Act requires slaughter-houses to be licensed and also in feeding of hogs offal to be boiled and fed fresh under penalty. Reasons given for believing the slaughter-house and piggery a nuisance, and indicating powers and duty of Local Board, also stated that the school authorities had been advised of my views.

June 2nd.—Secretary of Local Board replied, that Board had by resolution instructed Sanitary Inspector to notify all butchers to discontinue feeding offal unless boiled, and then fed in troughs. Inspector could not discover a nuisance.

June 4th.—Your Secretary was glad to know Local Board was acting, and advised a common slaughter-house for public slaughtering. If this is not done, action to abate nuisance and license must be taken.

June 8th.—Clerk replies that Board met on 7th and by resolution called attention of Town Council to By-law No. 5, prohibiting slaughter-houses within the municipality, and ask Council to enforce or repeal, and if repeal make new By-law under Provincial Health Act. Board denies wishing to injure butchers and advises a common slaughter-house.

June 8th.—Your Secretary compliments Local Board on action taken and looks for speedy action.

June 17th.—Clerk reports Council met on 13th but took no action on the communication; next meeting on 27th.

June 18th.—Your Secretary notified Town Clerk that the matter of a nuisance near school had by school authorities been laid before the Minister of Education, who had referred to your Secretary for information.

By law 5 of town prohibits slaughter-house within the town or the feeding of any offal. Date 1887.

June 28th.—Information sent your Secretary by school authorities that nothing whatever had been done to abate the nuisance by the Local Board of Health or Council, and believes that they will do nothing, hoping that all parties will let the matter drop. The butchers water their horses at the school well.

June 30th.—Your Secretary promises he will endeavor to have action taken.

June 22nd.—Department of Education is again appealed to, and asks if this Board cannot take the matter up independently of Local Board.

Such has been to date the total result of some 14 letters which have passed relating to this matter alone.

With such an exhibition of the utter break-down of municipal government we vainly seek for a remedy. Unless a dozen Inspectors of this Board were appointed with plenary powers to prosecute it would be quite impossible to deal with such evils, unless the local health machinery of our 250 incorporated municipalities undertake the responsibilities laid upon them.

One is compelled to conclude that our newspapers could profitably write many editorials, based upon that chapter, entitled "Political Control," in the recent work on street cleaning published by Col. George E. Waring, Commissioner of street cleaning in the City of New York.

With regard to the improvement of cheese-factories when prominent cheese men appealed last winter to your Secretary to aid in the inspection of the 1,100 factories in the Province he suggested appealing to the Local Boards.

The reply was a laugh at the idea, with the remark, that members of such boards in townships are usually directors and patrons of the factory. In our villages the local butcher and drover are commonly potent factors in deciding events on the first Monday in January.

At present, the only hope of improved conditions seems to be the slow process of educating the people, not to an appreciation of the evil so much as to a recognition of their responsibilities, powers and duties as citizens, or the placing of the power in the hands of a trained county officer of health, paid to do the work, and protected in the performance of it

All of which is respectfully submitted.

[Signed] P. H. BRYOE,
Secretary.

REPORT RE MEAFORD CEMETERY.

By P. H. Bryce, Secretary.

Toronto, April 20th, 1898.

To the Chairman and Members of the Provincial Board of Health :

GENTLEMEN,—As will be seen from the correspondence herewith submitted, it is proposed to establish a new cemetery, owned and managed by a company seeking incorporation under the Act relating to Cemetery Companies, on a property within the limits of the Town of Meaford, although, as will be seen from the map herewith submitted, practically outside the town and with its drainage toward a direction away from the settled part of the town and toward the lake. Your Secretary is acquainted with the topography of the town, and has not deemed it necessary, before submitting the application for your approval, to make a special inspection of the ground.

The Local Board of Health and the Town Council of Meaford have, as seen in the correspondence submitted, passed resolutions approving the site, and the consent has also been obtained of all persons living in proximity to the proposed site to the location of a cemetery thereon. As will be seen by the plan the cemetery is to be located on the ridge of hills which dips sharply northward to the shore of Georgian Bay. Apart from its present location, an admirable opportunity is given for the sub-soil drainage of the area.

Your Secretary would therefore recommend that the Board approve of the site of the proposed Meaford cemetery with the understanding that the company complies with the requirements of the several Cemeteries Acts in the matter of drainage and other particulars as are indicated therein. The report was adopted.

REPORT ON TEMPORARY SCHOOL ACCOMMODATION, UNDER PUBLIC SCHOOL BOARD, TORONTO.

By P. H. Bryce, M.A., M.D.

Toronto, May 6th, 1898.

To the Honorable, the Minister of Education of Ontario :

SIR—I beg to report that acting under instructions received from you, I have visited, in company with the Chairman of the Toronto Public School Board and officers of the Board, the several buildings referred to in the appendix to this report, occupied as temporary schools under the supervision of the Board, and have set down in a tabulated form therein the results of my inspection. The several points bearing upon the sanitary condition of these buildings are indicated in the Appendix, but may be briefly referred to herein.

They refer to

(a) Floor space and cubic air space per pupil ; (b) Play ground and location of school ; (c) Ventilation and conveniences ; (d) Lighting ; (e) Heating.

(a) With regard to floor space, 18 school rooms out of 29 inspected, have less than 16 square feet per pupil, the amount generally considered necessary. As in addition to this, the seats are usually double, it will be seen that even in cases, as in some of the churches where the cubic air space reaches or exceeds this amount, the contact of children

by such means materially increases the danger of the spread of communicable diseases from one to another. In the matter of the cubic air space per capita, 23 out of 30 school rooms have less than the 250 cubic feet required under the School Regulations.

(b) As regards playgrounds, 12 out of the 29 classes have no playground, unless it be the public streets, and in several instances as where stores are occupied, the schools are on streets along which street cars run. In such instances, as in a number of them, the stores or dwelling houses have the doors and windows directly on the streets, and the noise from passing cars and wagons must be a very serious obstacle to the proper conduct of the school, and indeed is very injurious to both teacher and pupils.

Under such circumstances, the much needed recess to escape the foul air of the school room has its good results greatly lessened, and as the classes in almost every instance are of the smaller children, this condition must on some streets become a source of danger to the pupils and a worry to the teacher.

(c) Except in two buildings (with four classes) there is no mechanism for artificial ventilation. In all other cases there is no ventilation but by windows and by stoves (not always even stoves), occasionally assisted by a stove-pipe hole, or in the sheds on the school premises a register in the chimney shaft. As the stoves were without fires in most cases, there is left at this season only the windows, and these both because of the noise and draught were in many instances tightly closed.

As will be seen by reference to the Appendix the cubic air space exceeded in seven instances the minimum required by law. These were in all cases church rooms, and had they been fitted up with good black-boards and proper lighting, they would be excellent.

In most instances the closet conveniences were not objectionable, although in five their location was such as to make odors from them likely to be noticed in the school rooms or corridors.

(d) The lighting in four only out of 29 is noted as "fair;" in the others it is "defective," or "very defective. The defects are due to five different causes:

1st. Where churches are utilized, the windows are usually narrow and too few, and in many instances have frosted or colored glass, and in a number colored lights at top and sides.

2nd. The proximity of windows to other buildings or to trees.

3rd. Low windows are in the sheds, where the position of the shed makes the proper location of windows impossible.

4th. The area of windows in basements. In some roomy basements, except as to obstructions to light from steam pipes, not more than three feet of window is above the ground level, and in some north rooms the teacher has to make writing with letters three inches long that they may be seen, and then imperfectly by the pupils in the back benches.

5th. The cross lighting in nearly all the basements and sheds, and the blackboards in shadow making it quite impossible in almost every instance for all the pupils of the class to see the whole extent of the blackboards.

(e) The heating in most instances seemed fair; but the season made this impossible of determination. It may be stated however, that the heating with stoves in one corner of the room presents the invariable objection of improper distribution of heat. In very many cases, as in the sheds, the wide window, hinged at the bottom, cannot be opened in winter without the cold air pouring down on children near by, while in one instance the furnace pipe was within one foot of a seat, and in the sheds and in some basements a stove-pipe passed within a few feet of the children's heads. The furnaces in the stores and dwelling houses may warm, but as there were no fresh air boxes in some instances, the reheating of room and cellar air is inevitable.

Conclusions. By reference to the Appendix, it will be seen with regret that not a single room does in all the several points fulfil fairly reasonable requirements. If ample in air space, it is defective in lighting; if in lighting fair, then in air space and ventilation.

In some instances it was plain that some intelligent care on the part of the teacher in adjusting window curtains would have increased the light or lessened the evils of cross-lights; while in others the judicious opening of a window would have, in the weather at the time of inspection, lessened the evils of foul air. But such a remedy for bad ventilation would be impossible in cold weather. In one instance where the air was very foul, not a window was raised, while a door into the attic space was tightly closed. In the greater number of instances, however, the teachers seemed to keenly appreciate the needs of the situation, and were doing their utmost to minimize evils. If, however, pale and wearied looking faces are to be taken as evidences, then it can only be said that such unsanitary conditions are producing results on both teachers and children, demanding a prompt and effective remedy.

But further it may be said that if the influences of vitiated air and defective lighting show themselves most prominently in affecting the health of the teacher, whose nervous energies are taxed to perform her work under such circumstances, they likewise affect that of the children under her charge. It will be noted that in only two or three schools is the lighting fair, and in most the air is bad or very bad. The immediate effects of foul air are to injure the nutrition of the child. The appetite and digestion are disordered, and every tissue, and primarily the nervous system, is affected. Since of all organs, the eye during waking hours is alone constantly in action, and nature has given it and its appendages nerve supply from the whole or parts of six out of the 12 pairs of cranial nerves, it will be apparent that defective nutrition will most readily be productive to it of serious disorders. Indeed actual disease of the retina has been found to have a direct relation to the poverty of the blood. Actual medical experience has shown that in 100 consecutive cases of chronic headache, 83.6 per cent. have been relieved by correcting the eye strain by proper glasses. What influence school work has in producing such abnormal vision has been illustrated by Widmark of Stockholm. Of 742 female pupils in the first forms, he found no myopia (short sight); while the percentage of short-sight in girls at 16 was 33 per cent. We may from such illustrations judge of what effects are being produced in these schools; first from the defective lighting, and second by the effects of foul air upon children for whom the teaching ought to be largely by blackboard. Teacher after teacher tells the story of how pupils, who at first could see the blackboard from the back seats, have as time has gone on had to be given seats nearer and nearer the front. The eye-strain soon produces mental weariness, and favorable results of the teacher's efforts cannot be looked for. The general disturbance of the nervous system, notably in girls, by eye-strain must inevitably produce effects life-long in their unfortunate results, and the continuance of the existing state of affairs cannot be condemned too strongly, affecting as it may the welfare of so large a number of children.

The extent of the need for a remedy for these existing evils will be understood when I state that 1,510 children were in actual attendance at the time of inspection, or one-twentieth of the total 30,000 public school population is unprovided with permanent school accommodation. When it is further remembered that the natural increase of births over deaths in Toronto, means an annual increase of population of over 1,000 (it being 1,278 in 1876), it is plain that there must be an annual expenditure for new buildings, otherwise conditions, now very bad, will become intolerable.

In the Annual Report of the Public School Board for 1897, I find it stated that during the past three years there have been no new school buildings erected in Toronto. There would not appear to be any difficulty in closing a number of these schools by taking action under the provisions of the Public Health Act, but I am assured by the Inspector Buildings that he has used every endeavor to get public halls and churches, instead of

stores and private houses in several districts, but failed. There seems no alternative therefore, but during the warm weather to allow these schools to be continued where they are at present, in order to prevent a loss of school privileges to a very large number of children.

While suggesting this as a temporary expedient, I would recommend that your Department should put in operation whatever powers exist under the Public School Act, to bring about such a remedy for the state of affairs herein indicated, as will be permanent in its character.

I have the honor to be,

Your obedient servant,

PETER H. BRYCE,

Secretary of Provincial Board of Health.

School.	Location.	Attendance.		Cubic air space. Playgrounds.	Ventilation.	Conveniences.	Lighting.	Heating.
		Re- g.	Ave.					
Bathurst street..... Kindergarten.	Shed	76	60	Playground of school, 130 sq. feet floor space, 145 cubic ft. air space.	Windows on n.e. hinged at bottom, not avail- able in winter, air close.	Closets out doors, Lat- rines.	Low windows on north and east, light very defective.	Stove.
Clinton street..... Kindergarten.	Church S. S.	72	63	Street principally. 12 ft. floor space, 134 ft. air space.	Windows (closed) one vent in ceiling (closed), air very foul.	Closets off passage, not ventilated, smelling.	Four windows south and west, light fair.	Furnace.
Sheridan street..... Kindergarten.	Church proper....	38	38	34 ft. floor space, 443 ft. air space.	Double windows only (closed), air is warmed in furnace, large cubic air space.	Earth closets	Windows are narrow, east and west, light poor.	Furnace reheat- ing air of room.
St. Claren's ave..... Kindergarten.	Church S. S.	65	41	Street. 15 feet floor space, 153 feet air space.	Windows only (closed), door open at time of visit.	Water closet in cellar.	Windows west and north, small.	Furnace in base ment.
Shirley street	Old building, two- room, s. w. and s. e.	54 54	46 47	Grounds of school build- ing, 12 ft. floor space, 176 ft. air space, 12 ft. floor space, 176 ft. air space.	Windows only, door open at noon hour, rooms very old and small, air foul.	Closets of main build- ing, air in one room main building foul, in- let of furnace duct closed.	Lighting fair, window s.w. and s.e.
Grace street..... Junior 1st class form.	Basement of school building, s. w. room.	56	54	Low ceiling (8 ft) sleep- ers of floor resting on earth, playground of school and also in base- ment. 14 ft. floor space, 111 ft. air space.	Windows only (none open), cloaks hanging in room, air poor.	Closets (Smead-Lowd) splendid order.	Windows south and west, 4 feet in height light fair, but on du- day children cannot see board.	Stoves.
Dewson street..... (a) First class.	Shed	47	45	School grounds no play sheds. 15 sq. ft. floor space, 164 cubic ft. air space.	Windows, registers near floor in chimney shaft, air foul.	Closet of school.....	Four shallow windows; light poor, cannot see blackboard from a dis- tance.	Stove.
(b) Second grade	Shed	44	42	16 square feet floor space, 176 cubic ft. air space. Same as above.	Same as above, air foul.	Same as above.....	Same as above.....	Stoves.

Gladstone ave. (a) Junior 2nd form.	Shed	54	11 square ft. floor space, 110 cubic ft. air space. School grounds.	Windows hinged at bottom, low and with outside screens, regis- ter near floor in chim- ney shaft, small area, air foul. Same as in (a).	Closets of main build- ing.	Windows one south, three west, low and wide, only 10 feet from a house, lighting de- fective.	Stove.
(b) Senior 1st form	Shed	53	11 square ft. floor space, 116 cubic ft. air space. Same as in (a).	Same as in (a).	Same as in (a)	Windows west, light fair, only 25 feet from a privy.	Stoves.
(c) Junior 1st form	House	47	7 square ft. floor space, 72 cubic ft. air space. No play ground.	Windows only, down, air very foul and stifling.	House closet up stairs.	Double room, long and narrow bay window to east. In parts very defective.	Furnace.
(d) 2nd form	Store	48	10 square ft. floor space, 107 cubic ft. air space. No play ground.	Windows only (closed) air foul, cloak room separate.	Closet of store	Lighting to east, defec- tive.	Furnace.
(c) Senior 2nd form	Store	47	10 square ft. floor space, 122 cubic ft. air space. No play ground.	Same as (d).	Same as (d)	Same as (a).	Furnace.
Dundas street, No. 47 (a) Junior 2nd form.	Store	46	12 square ft. floor space, 145 cubic ft. air space. No playground.	Windows and transoms over door.	Closet in basement di- rect under stairway.	Window to west, with upper part colored, light very defective.	Furnace.
Dundas street, No. 41. (b) Junior 1st.	Store	48	12 square ft. floor space, 149 cubic ft. air space. Same as (a).	Same as (a).	Same as (a)	Same as (a).	Furnace.
Ryerson school (a) First class.	North-west base- ment.	66	16 square ft. floor space, 146 cubic ft. air space. School ground.	Windows only, ceiling 7 ft., floor on joists on ground, air bad.	Closets of Smead-Dowd system.	Windows north and west, 3 feet above ground, writing on board to be 3 in. long to be seen at any dis- tance, greater part of the room in shade.	Steam pipes and with stove.
(b) Senior 1st class	North-east base- ment.	*28 *26	39 square ft. floor space, 341 cubic ft. air space. Playground same as (a).	Ventilation same as (a) air fair.	Same as (a).	Lighting north and east, same conditions as (a), very defective.	Same as (a).

* Teachers report large scholars staying away on account of condition of rooms.

Ryerson school.— <i>Con.</i> (c) Kindergarten	South-east basement.	*80	*62	13 sq. ft. floor space, 107 cubic ft. air space. Playground of school.	Same as (a) and (b), air poor.	Same as in (a)	Same as in (a), except much better light, windows being south east, fair.	Same as (a).
Claremont street mission	Church S. S.	41	36	27 square ft. floor space, 487 cubic ft. air space. No playground.	Windows, air fair, space large.	Closet	Narrow windows, with stained borders, two to south, two to north near a house; windows average 10 square ft.; some light from skylight, very defective.	Furnace.
Dufferin school	North-west basement of school.	*58	*54	16 square ft. floor space, 137 cubic ft. air space. Playground of school.	Windows and ventilators; air only fair.	Closet	Three windows to west only 3 ft. from ground; 4 steam pipes cross upper part of windows; light poor.	Steam pipes and stove.
(b) Kindergarten	South-east and south-west rooms of basement.	83	75	22 square ft. floor space, 190 cubic ft. air space. School ground.	Windows also, with steam coil in ventilator shaft; air very good.	Closet	Same as in (a), south and east windows; light fair.	Steam heating.
Oak street church	Upstairs Sunday school room, 2nd class separated by curtain in same room.	60	53	19 square ft. floor space, 318 cubic ft. air space.	Windows and high ceiling in gable; air very good.	Smead-Dowd system ..	Five windows north and east, two west; light defective; children in each room face towards light.	Smead-Dowd furnace.
Senior 1st form	2nd class separated by curtain in same room.	45	40	26 square ft. floor space, 421 cubic ft. air space. No playground.	Windows and high ceiling in gable.	Ditto	Ditto	Smead-Dowd furnace.
Prospect Park Rink Kindergarten.	Club room	68	48	17 square ft. floor space, 225 cubic ft. air space. No playground.	Windows, no ventilation; air foul.	Closets close to hall ..	Three windows west, two windows north; good light.	Furnace.

Bolton avenue..... Junior 1st.	61	49	30 square ft. floor space, 485 cubic ft. air space. No playground.	Windows ; ventilators over gas jets.	Closet.....	Three windows to south, as well as sky- light and fanlight. Fair.	Furnace.
Pape avenue, No. 484... Junior and Senior 1st.	33	30	13 square ft. floor space, 132 cubic ft. air space. No playground, except neighboring field.	Windows; one fanlight hinged; air very foul.	Water closet.....	Small windows, light shut off by house dis- tant three feet; one square window with colored glass above, most of room in shadow; light most defective.	Furnace.
Carlaw avenue..... 1st form.	46	41	19 square ft. floor space, 248 cubic ft. air space. No playground.	Windows and gable ; ventilation poor, aid- ed at present by doors open to next room.	Water closet....	Six windows, south light cut off by trees and house; two square windows to west; trees near.	Furnace.
Kenilworth avenue..... (a) 2nd, 3rd and 4th forms.	52	52	15 square ft. floor space, 228 cubic ft. air space. Playground on com- mon.	One small round win- dow on hinge in gable end ; air foul.	Closet.....	Four windows east, four windows west, stained yellow glass, stained borders, six inch squares ; lighting very defective.	Furnace.
(b) Junior and senior form	42	31	10 square ft. floor space, 106 cubic ft. air space. Playground on com- mon.	Windows open verti- cally, not open on ac- count of draught ; one stovepipe vent ; air very foul.	Windows south, east and west, lower half of windows stained glass ; light good if regulated.	Furnace ; stove- pipe within one foot of seats.

* (Average 70). Two sets of children, one in forenoon, one in afternoon (170 daily).

† Only 48 seats, balance on wall benches.

REPORT *RE* INSPECTION OF SCHOOL IN TRAFALGAR TOWNSHIP

By P. H. Bryce, M.A., M.D.

To the Chairman and Members of the Provincial Board of Health :

GENTLEMEN,—At the request of the Local Board of Health, I visited the school at the Union Section on the 9th concession of the Township of Trafalgar on May 27th, and addressed the following report to Dr. N. McCrimmon, M. H. O. of the township: I beg to state that careful investigation, with yourself, failed to find any unsanitary conditions on the premises likely to provoke an outbreak of diphtheria, such as the outbreak which occurred in April, the particulars of which were so fully obtained by yourself, with me, from the trustees, Messrs. Cook and Fullerton, and the young school mistress.

The closets are earth closets, and show evidence of close supervision, while the location of the well is such as to have made it impossible for any pollution other than what might have accidentally reached it from the surface. I would suggest that if a new well is dug it be tightly covered, with an air pipe leading in, and that the pump be placed at a distance from the well and connected by an iron pipe, covered to keep out the frost.

More ventilation of the foundation of the school than was found, is necessary to keep the joists dry.

By a careful enquiry as to the dates of the appearance of cases of diphtheria amongst scholars and neighboring families, as well as by examination of absentees as seen by the roll, there seemed fairly clear evidence of the outbreak being connected with a case or cases of sore throat of a mild character which had not been detected. Thereafter, the evidenced was closely connected with the return of children to school after Easter, who were again exposed to some case or cases who were convalescent but not free from infection in the nose and throat.

The recommendations are to have:

1st. The floors scrubbed with a strong alkali soap.

2nd. The wainscoting washed down with disinfectants under the supervision of the Medical Health Officer.

3rd. The disinfection of the seats and desks in the same manner.

4th. The disinfection of school books by steam, will in my judgement, prove adequate to the removal of any infection which might possibly, though not probably, have remained in the school. And I do not anticipate any re-appearance of cases, unless brought to the school in the clothing of some person, which has not been properly disinfected.

THE VALUE OF SANITATION AS AFFECTING THE BIRTH RATE AND OF POPULATION INCREASE.

BASED ON A STATISTICAL STUDY OF VITAL STATISTICS OF TORONTO, MONTREAL,
CHICAGO AND PHILADELPHIA.

By J. J. Cassidy, M.D., Toronto.

To the Chairman and Members of the Provincial Board of Health :

GENTLEMEN,—It is interesting to make comparison between the vital statistics for 1897 of Toronto and Montreal, in Canada, and Philadelphia and Chicago, in the United States, in order to estimate the facts which underlie the natural increase of population in these cities. In Montreal, with a population of 262,100, the total births for 1897 were 8,850, or 32.43 per 1,000 of population. In Toronto, with a population of 183,172, the births were 4,076, 22.25 per 1,000. In Philadelphia, with a population of 1,214,256, the births were 29,591, or 24.37 per 1,000. In Chicago, with a population of 1,619,225, the births were 28,158, or 17.39 per 1,000.

In reference to the high birth rate of Montreal, Dr. Roy, Recorder of Statistics, writes that "he only gives the number of those who have been registered, and that owing to a defect in the law, registration among those who do not have their children baptized is not regularly done." In reference to the birth rate of Chicago, Dr. Reynolds, Commissioner of Health, of that city, writes that he does not get all the births that occur, probably not over 90 per cent., possibly not over 80 per cent. Occupying middle ground, Philadelphia maintains a fairly high birth rate, 24.37 per 1,000. The surprising part of the record is the relative showing of Toronto, with a birth of 22.25 per 1,000, higher than that of Chicago, but lower than that of Philadelphia.

The marriage rate of Montreal, 6.9 per 1,000, not only does not explain the high birth rate of that city, but makes it the more surprising. It seemed possible that a considerable percentage of illegitimate births might account for the high birth rate and low marriage rate. This, however, is not the reason. Through Dr. Roy, Recorder of Statistics, we learn that the illegitimate births in Montreal were 644, which sum being deducted from the grand total of births, 8,850, leaves 8,206, or a legitimate birth rate of 31.3 per 1,000.

In Toronto, the marriage rate, 8.19 per 1,000 is higher than in the other Canadian city. In Chicago, the marriage rate is 8.43 per 1,000.

In Philadelphia, the marriage rate, 12.67 per 1,000, is highest of any of these four cities being nearly double that of Montreal.

In Chicago and Philadelphia, premature and still births are excluded from the death rates. In order to compare, on even terms, with these cities, we shall eliminate the premature and still births from the death returns of Montreal and Toronto. The deaths in these cities are as follows: Montreal, 6,939, a ratio of 26.47 per 1,000; Philadelphia, 22,375, a ratio of 18.72 per 1,000; Toronto, 2,873, a ratio of 15.68 per 1,000; Chicago, 21,809, a ratio of 13.46 per 1,000.

The increase of births over deaths depends on two chief factors; either an increase of the birthrate or a decrease of the death rate. The following table makes a comparison between births and deaths in these cities during 1897, with the natural increase:

City.	Population.	Increase of Births over Deaths.	Percentage of Increase.
Montreal.....	262,100	1,911	.0072
Toronto.....	183,172	1,203	.0065
Philadelphia ..	1,214,256	7,216	.0059
Chicago.....	1,619,226	6,349	.0039

The highest of these percentages, that of Montreal, is a trifle under three quarters of one per cent. Now, according to the estimated rate given in the annual report of the Registrar-General for England and Wales, the natural increase for that country for 1890 is $1\frac{1}{2}$ per cent., and the report for 1891 states, that the same rate was maintained for that year. The natural increase in these cities is, therefore, small. Yet the effect of an immense birth rate is apparent when we see that Montreal, in spite of a large mortality, is able to show a greater increase than Toronto. Similarly Philadelphia, in spite of a relatively large death rate, shows a larger increase than Chicago.

During the year 1897, notable epidemics of preventable diseases did not prevail in these cities. Philadelphia had a mortality of 401 from typhoid fever; in Chicago, typhoid fever caused a mortality of 437, against 751 in 1896, an immense decrease. In contagious diseases, scarlatina caused a mortality of 66 in Toronto, and small-pox a mortality of 12 in Montreal. Moreover, the annual death rate of Philadelphia, 18.72 was, for a large city, quite normal; that of Toronto, 15.68, was also satisfactory.

Under these circumstances, the low death rate of Chicago and the high death rate of Montreal demand some explanation. An authority (Rohé) states, that in a large city, such as Chicago, a death rate of 13.46 "would indicate that all the deaths had not been recorded, or that the population had been over-estimated; rates above would be evidence, that there were special causes at work demanding sanitary investigation and improvement." Without undertaking to dispute these assertions, it may be well to point out that the Chicago Department of Health, which in 1897 was carried on at an expense of \$213,560, maintains a special bureau of vital statistics, and certainly ought to be informed of every death which occurs in that city. The statistical population figure used is the official school census declared July 1st, 1896. In Chicago, moreover, the proportion of adults to children is, probably, greater than the normal, and the death rate is naturally lower. Besides, great efforts are being made in that city to put down disease and promote good health, so that owing to the social condition of many of the people, and civic sanitary improvements as well, a low mortality is quite conceivable.

A survey of the diseases, which produce the large mortality of Montreal does not reveal many causes demanding special sanitary investigation. In 1897, there was an outbreak of small-pox, which caused twelve deaths, and the death rate from other zymotic diseases, is not high. The following table shows the typhoid fever mortality of the four ties, with the ratio per 100,000 of population:

	Deaths from typhoid fever.	Ratio per 100,000.
1897. Toronto.....	20	16.37
Chicago.....	437	26.98
Montreal.....	80	30.52
Philadelphia.....	401	33.02

Here, we may admit that the Montreal ratio assimilates too closely to that of Philadelphia to be reassuring. It may be, therefore, that the Montreal water works demand sanitary investigation and improvement, or the large typhoid mortality may be explained in a different way. In order to show the mortality from zymotic diseases, whose incidence falls most on children, in a city with a high mortality, compared with a city having a low mortality, the following table is submitted:

1897. Montreal—Deaths from variola.....	12
“ “ mumps.....	00
“ “ measles.....	63
“ “ scarlatina.....	17
“ “ whooping-cough.....	95
“ “ diphtheria and croup.....	251
	<hr/> 438

Or 6.3 per cent. of the total mortality.

1897. Chicago—Deaths from variola.....	00
“ “ mumps.....	4
“ “ measles.....	139
“ “ scarlatina.....	81
“ “ whooping-cough.....	160
“ “ diphtheria and croup.....	772
	<hr/> 1,156

Or 5.3 per cent. of the total mortality.

Here, an advantage of 1 per cent., on the side of Chicago, shows, that measures for the suppression of contagious diseases were more successfully carried out in Chicago, than in Montreal. It is only fair to say, however, that in Montreal, on account of a high birth rate, there are more candidates for contagious diseases, and, consequently, greater difficulty is experienced in checking outbreaks of these diseases than in Chicago. Some other factor than insanitary conditions seems, therefore, necessary to explain the high

death rate of Montreal. It seems to be due to a large mortality among infants and young children, particularly the former. For instance, the deaths of children under five years of age in Philadelphia were 7,605, or 33 per cent. of the total mortality. In Toronto, the deaths of children under five years of age were 998, or 34.73 per cent. of the total mortality. In Chicago, the deaths of children under five years of age were 8,546, or 39 per cent of the total mortality. In Montreal, the deaths of children under five years of age were 3,273, or 47.16 per cent. of the annual mortality. In Montreal the loss of infantile life appears to be excessive. The actual figures are:

1897. Montreal—Total mortality.	6,939
Deaths under one year.....	2,306—33.23%
Deaths from one to five years.....	967—13.93%
	<hr/> 3.273 or 47.16%
1897. Chicago—Total mortality	21,809
Deaths under one year.....	5,735—26.29%
Deaths from one to five years.....	2,811—12.88%
	<hr/> 8,546 or 39.17%

The mortality rate for children from one to five years of age is better, by over 1 per cent., in Chicago than in Montreal; but the great divergence appears when we compare the respective mortality rates of children, under one year of age. Under this head, Montreal has a mortality of 6.94 per cent. larger than that of Chicago. This does not mean that infantile life is more carefully preserved in Chicago, than in Montreal. The death rate among infants bears a relation to the birth rate; in cities where the birth rate is high, the infantile death rate is high, and where it is low, the infantile death rate is low.

Among the causes that make the mortality among infants and children high are: Parents too young or sickly, hereditary taints, unhealthy environments, improper and insufficient food and clothing. It is, simply the manifestation of the workings of the law of the "survival of the fittest." As evidence of the soundness of this view, we may say, that in Montreal, 658 deaths were due to congenital debility, 129 to infantile convulsions, 310, a large number of which were in children, to simple meningitis, and 1,396, the greatest number of which were probably in infants and children, to diarrhœa and gastro-enteritis, which was the highest single factor in the death rate of Montreal. If to these we add the number of infants and young children, who perished from zymotic diseases, we can see how the large mortality is produced. When contagious disease appears in Montreal, it is all the more necessary for the health authorities to exert themselves and enforce good hygiene in the domicile and the school, so that though the congenitally weak may perish, the largest number of those, who are fit and strong, may be spared to reach adult age.

REPORT OF THE COMMITTEE ON VENTILATION.

By J. J. CASSIDY, M.D.

TORONTO, January 31st, 1899.

To the Chairman and Members of the Provincial Board of Health :

GENTLEMEN,—On Monday, January 16th, your committee tested the heating and ventilation of the Public and High Schools of Caledonia, which are included under one roof. The plan and specifications of this system of ventilation are herewith submitted : or, this system may be thus described ; a cowl in a turret at the roof, revolves with the wind, and catching air from whatever quarter the wind blows, delivers it through inlets into the rooms to be ventilated. The incoming air may be heated in winter by a stove, hot water coils or a furnace. After distribution the air is removed through heated outlets at the floor level, which cause it to ascend and escape in the turret, in a direction contrary to the wind. Suggestions are offered in Mr. Shantz's report, about purifying the incoming air by filtration and for cooling the air in summer. The combined outlet pipes may be heated by the smoke stack of the furnace. At Caledonia, as stoves are used, the stovepipes enter flues in the walls in the ordinary way, but they serve to heat the initial portion of the outlet in each room and help to create a current of air. The fresh air descends into each room, enters an area surrounding the sides and the bottom of a box-stove and escapes into the room. The tests applied are herewith submitted :

REPORT OF VENTILATION OF PUBLIC SCHOOL AT CALEDONIA.

Date, January 16th, 1899.

660 feet above sea level.

Weather, fair and mild ; wind, south by west.

Temperature, 42° F. ; humidity, 73% ; barometer, 29.10 inches.

Room No 1 ; floor, 1st ; side, north-east.

Seating capacity, 50.

Persons present, 25.

Net air space, 9750 cubic feet.

Air space per cap., 390 cubic feet.

Temp. at teacher's desk, 64.° F.

Humidity, $\left\{ \begin{array}{cc} \text{D.B.} & \text{W.B.} \\ 73^{\circ} & 63^{\circ} \text{ F.} \end{array} \right\} 54\%$

Different temperature in different parts of room at breathing line, 71.64°=7° diff.

Temperature of air at inlet, 98° F.

Fresh air per minute, 146 cubic feet.

Air removed at outlet per minute, 306 cubic feet.

Amount of air supplied per cap. per minute, 5.84 cubic feet.

Air of room changed 1.9 times per hour.

Carbonic acid in 1,000 parts of air, 1.025 (3rd filling); pure air out doors, 12 fillings.

Time of test, 10.35 a.m.

REPORT OF VENTILATION OF HIGH SCHOOL.

Date, January 16th, 1899.

Weather, fair and mild ; wind south by west.

Temperature, 43° F. ; Humidity, 75% ; Barometer, 29.05 inches.

Room No 1, ground floor, west side.

Seating capacity, 62.

Persons present, 37.

Net air space, 9,000 cubic feet.

Air space per cap., 240.32 cubic feet.

Temperature at teacher's desk, 61° F.

Humidity, D. 61° F., W. 53° F.=60%.

Difference in temperature in different parts of room at breathing line, 61 65° F.=4° F. average difference.

Temperature of air at inlet, 75°.

Fresh air per minute, 118.3 cubic feet.

Air removed at outlet per minute, 232.050 cubic feet.

Amount of air supplied per cap. per minute, 3.20 cubic feet.

Air of room changed=1.54 times per hour.

Carbonic acid in 1,000 parts of air, 1.230 (air close).

Time of test, 2.45 p.m.

In Public School room 1, first floor, the cubic air space per capita, 390 feet, was rather large, but this was due to a small attendance, twenty-five instead of fifty pupils. The temperature ranging from 71° to 64°, showing a difference of 7°, indicated a rather uneven distribution of warmed air. The humidity, fifty-four per cent., was good, especially when compared with the humidity of air supplied by a hot air furnace, which commonly supplies air having a humidity of forty-two to forty-five per cent.

The quantity of fresh air supplied per minute, 146 cubic feet, or 5 84 cubic feet per capita was very small, the standard being thirty cubic feet per capita per minute.

The air of the room was changed in 1.9 times per hour for twenty-five pupils, it should have been changed 4.61 times. The air was rather close, containing carbon dioxide 1.025 per 1,000 vols. In High School, room 1, ground floor, the net air space, 240.32 cubic feet, was less, the number of persons present being greater and the room a trifle smaller. The small difference, 4°, between the highest and lowest recorded temperatures showed an even diffusion of warm air. The humidity, sixty per cent., was favorable. As in the other room, the amount of fresh air admitted was small, the amount supplied per capita per minute, viz., 3.20 cubic feet, being about ten times less than the full amount. The air of the room was changed in 1.54 times per hour, when it should have been changed in 7.4 times per hour. The air was close, the carbon dioxide being 1.230 in 1,000 volumes of air. It was necessary to open the windows to let in fresh air.

The system provides an equable flow of warmed air through a room. In order to produce standard effects as a system of ventilation, it would be necessary to make the inlets large enough to admit the required amount of fresh air and the outlets wide enough to remove a corresponding amount of foul air, and to produce the necessary rapidity of movement fans would be required.

Mr. Shantz informed me that his system would work better on a windy day. He also proposed making certain changes in his system in order to make it more effective.

Mr. Tracy's heating drum and ventilator is an apparatus which may be described as follows: A sheet-iron drum 28½x13 inches, placed above an ordinary base-burner stove, so that the smoke pipe of the stove passes through the centre of the drum; an outlet pipe 2½ inches in diameter, starting from a point two inches above the floor, ascends and perforating the lower surface of the drum discharges air drawn from the floor level directly into the common smoke pipe. A fresh air inlet, 3¾ inches in diameter, starting outside the house wall, discharges warmed air into the room. This system was tested by Dr. Bryce as to the temperatures obtained in different parts of the room and also the inflow and outflow of air.

December, 13, 1898, 3 p.m.—Outdoor temp., zero; room, ground floor, south-east corner Yonge and Shuter streets. Capacity, 56,700 cubic feet. This space was heated by a base-burner coal stove, to which a Tracy drum was attached. The following temperatures were taken:

Temperature: 6 feet from stove, 5 feet above floor, 48° F.

Temperature: 25 feet from stove, at ceiling, 48° F.

Temperature: 80 feet from stove, 7 feet above floor, 46° F.

Temperature : 22 feet from stove, on floor under north window, 40° F.
 Temperature : 40 feet from stove, on floor under north window, 40° ; on floor near
 foul air outlet, 48° F.

Temperature : 40 feet from stove, to north-east 2 feet from floor at window, 40° F.

Temperature ; 60 feet east of stove, 2 feet from floor, 40° F.

Temperature : 6 feet east of stove, 2 feet from floor, 45° F.

Temperature : 40 feet to east of stove, 5 feet from floor, 43° F.

Temperature : 45 feet to east of stove, 5 feet from floor at a window, 43° F.

Temperature : 5 feet from stove, 5 feet from floor, 47° F.

Temperature of fresh air at inlet, over, 150° F.

December 14th, the extraction of foul air was measured and was found to be
 17.18 cubic feet per minute or 1,030.83 cubic feet per hour.

The air space would be changed in fifty-five hours.

The fresh air inlet delivered 15.46 cubic feet per minute or 927.75 cubic feet
 per hour.

We thus see that the small quantity of fresh, warm air introduced by this system
 into the room, viz., 927 cubic feet, is almost equal in amount to the quantity removed at
 the outlet, viz., 1030 cubic feet. The slow, equable inflow and outflow secures an even
 diffusion of the air heated by the stove in all parts of the room as shown by the recorded
 temperatures given above.

This system deserves favorable notice as a simple and efficient method of causing
 the air, heated by a common stove, to circulate freely throughout all parts of a room, the
 lower levels of a room being maintained at about the same temperature as the space near
 the ceiling. It is suited for the moderate heating of a relatively large air space, in
 which it is desirable to obtain the required heating of the air with one stove. It is not
 a system of ventilation, because the quantity of fresh air introduced is very small, but
 ventilation or the inflow and outflow of air are dexterously employed to provide for the
 equable diffusion of warmed air.

Your committee has also received a paper and a sketch from Mr. J. Dearness,
 County School Inspector, London, Ont., describing a system of heating and ventilation
 used in several schools in that portion of the Province. This system in brief provides
 for the introduction of pure air into a drum fitted on the end of a large box-stove, where,
 being heated, it is distributed in the school room. The foul air is removed at the floor
 level by flues, ascending from the floor, a current being created in them by the heated
 smoke-stack of the stove, which runs through the common terminal foul air outlet and
 afterwards penetrates through the roof.

This system is said to have produced good results in heating the buildings in which
 it is used and with a saving in the matter of fuel.

Not having tested the ventilation in any of the schools, heated by this system, your
 committee cannot express an opinion as to its merits as a system of ventilating a school
 room.

PART III.

BELLEVILLE.

REPORT OF THE MEDICAL HEALTH OFFICER.

Nov. 1st, 1898.

To the Chairman and Members of the Local Board of Health :

GENTLEMEN,—I have the honor to present the following report for the year ending 30th November, 1898 :

The mortality for the past year was 137. Of these three died from typhoid fever which was contracted out of the city, fifteen cases of phthisis from city and county, twenty-one cases of pneumonia, four cases of cancer, three still-births, four cases of appendicitis ; there has not been a death from either scarlet fever, measles, whooping cough or diphtheria during the year.

The Inspector made his usual house to house inspection of the city and found the citizens willing and anxious to respond to the requirements in the way of cleaning up yards and privies. We are gradually closing up privy pits and adopting dry earth closets, and in time hope to see all pits abolished. The wells also were inspected and analysis of samples of water sent to Toronto, and any well found to be dangerous was ordered to be filled up. The city council is gradually extending the system of sewers, and I trust that in a few years Belleville will have a complete system of sewerage which will no doubt improve the city in a sanitary way. The Inspector has looked carefully after any complaints forwarded him by me, something over sixty during the year, and placarded any house with infectious diseases. The market square and street near it have been kept clean and free from any garbage, after each market being thoroughly swept and all refuse carted away. We have one slaughter house in the city which has been kept clean and no refuse matter allowed to remain on the premises twenty-four hours. We have had a few sporadic cases of scarlet fever, in each case the house was placarded and disinfection in the way of sulphur fumigation, so that in no case was the fever allowed to extend.

I have the honor to be,

Your obedient servant,

R. TRACY, M.D.,

Medical Health Officer.

BELLEVILLE, November 1st, 1898.

BRANTFORD.

REPORT OF THE MEDICAL HEALTH OFFICER.

Nov. 11, 1898.

To the Chairman and Members of Brantford Board of Health :

GENTLEMEN,—I herein beg to submit to you the annual report of the sanitary condition of the city for the year ending October 31, 1898.

Mortuary statistics.—The total number of deaths for the period comprised in this report has been 204, which in a population of 18,000, gives a death rate of 11.33 in 1,000, and as compared with previous years is a very satisfactory showing. The death rate per thousand in 1893 was 13.83 ; in 1894, 13.03 ; in 1895, 15.56 ; in 1896, 13.88 ; in 1897, 15.01. As to causes of death there was from typhoid fever, 7 ; diphtheria and croup, 3 ; pneumonia, 17 ; phthisis, 16 ; diarrhoea and cholera inf., 11 ; other causes, 150.

Of these there were under one year 41 ; under five years 52 ; over sixty years, 58 ; and over eighty years, eight.

Contagious diseases.—Of this or the so-called preventable class of diseases, there has occurred in the city during the past twelve months a total of 130 cases, or a decrease of 19 from the preceding year. The following table will give the monthly rate and mortality of each disease :

Month.	Typhoid fever.		Scarlet fever.		Diph. and croup.		Measles.		Unclassified.	
	cases	deaths.	cases	deaths.	cases.	deaths.	cases.	deaths.	cases.	deaths.
November.....	3	2	2	0	4	0	0	0	0	0
December.....	2	0	3	0	6	1	0	0	0	0
January.....	3	1	1	0	5	1	2	0	0	0
February.....	0	0	1	0	3	0	0	0	6	0
March.....	0	0	1	0	1	0	0	0	0	0
April.....	1	1	0	0	1	0	0	0	0	0
May.....	0	1	0	0	0	0	0	0	0	0
June.....	0	0	11	0	4	0	0	0	0	0
July.....	3	0	9	0	1	1	0	0	0	0
August.....	5	1	4	0	1	0	0	0	0	0
September.....	9	0	2	0	2	0	0	0	1	1
October.....	18	2	9	0	4	0	0	0	0	0
	44	7	44	0	32	3	2	0	7	1

Total cases, 130, and deaths, 12.

Typhoid fever.—During the past sanitary year there developed in the city 44 cases of typhoid fever, with the rather high mortality of 7, as compared with 31 cases and 4 deaths in 1897, and 55 cases with 5 deaths in 1896. Most of the cases have been confined to the eastern and northern portion of ward IV., where the water supply is principally from wells, the common source of which is springs in the low flat part of the ward and which at the same time receive a great part of the drainage from that part of the city. As seen from the above monthly record the greatest number of cases occurred during September and October, after the summer drought when the wells are at the worst. As the cause of typhoid fever is generally directly or indirectly attributable to the water supply, it has this year as in previous ones, been shown that the consumers of well water are more frequently infected than those who are users of the public water supply, since out of the above 44 cases, 35 were well water users, five both city and well, and four city water users.

Again, we find that in the most thickly populated parts of the city, where once typhoid was prevalent, since the abolition of the wells and replacing them with the public supply, typhoid is of rare occurrence. Thus the gradual extension of this process along with an efficient sewerage system in these infected regions will soon reduce the number of cases to a minimum.

Scarlet fever.—Of this disease, 44 cases with no fatalities, were reported during the year, and although the cases were of a mild type, there is more to be feared from the spreading of this than any of the other contagious diseases, from the fact that a mild case often goes unnoticed, no physician being called in. The child going to school becomes a source of general infection, and since the period of infection exists long after the patient is well and able to be about, it is practically impossible to enforce the required isolation outside a proper hospital; and more particularly is this the case in large families or such places as the children's aid home (where some 17 children are lived together) and from which institution we feared the development of a general outbreak during the last month from an infected child from these attending school, and which undoubtedly proved the source of a number of cases in that locality outside the five we were fortunate in restricting the number to within the home. Of other cases occurring in the city, ten were apparently due to the accidental infection of a milk supply through the bottles. This matter was speedily remedied and no further developments from that source occurred; other seven cases were directly traceable to direct infection from children playing together during the period of desquamation, which is the most infective period.

Diphtheria and Croup.—During the last year there were reported of the above 32 cases with three deaths, as compared with 42 cases and ten deaths in 1897. Of these four cases with one death occurred in houses previously infected.

Two of the public institutions have been visited by this disease during the year; the institution for the blind, where through the efficient mode of isolation, etc., but three cases developed; and the young ladies' college where one case occurred, but being promptly removed from the buildings no other cases developed. Both the above places received the infection from outside

the city by the return of pupils after the summer vacation. It is with diphtheria that we have been called upon twice during the year to deal with in the way of removal and isolation in different parts of the city, both cases being imported from the outside. Although the disease was prevented from spreading, yet at the same time it was the source of much trouble and annoyance, for to procure the necessary accommodation is next to impossible.

Isolation Hospital.—I wish once more to call the attention of this board and to solicit their prompt action towards the establishment of such an institution, the need of which this city with its increasing population seriously feels, and which to cope successfully with contagious diseases, we must have.

Measles.—This year we have had but two cases, with no deaths, as to 36 cases and two deaths last year.

Of other contagious diseases unclassified in the above there has been seven, with one death, that being from whooping cough.

Public Water Supply.—In this matter of public water supply, which affects to a very great extent the health of a community, we as a city are very fortunate, for not only is there a marked absence of such diseases as typhoid fever in those who use the city supply as compared with the users of well water, but the frequent tests of the Provincial Bacteriologist show the universal good quality of the city supply. For example, I give the last report taken from samples sent during the middle of September, when, if at any time, the report should be the most unfavorable. The results are as follows :

Health Office tap	Bacteria per cc.	20	
Victoria Park tap.....	"	32	
Alexandria Park.....	"	50	
Mohawk Institute well No. 1.....	"	580	
" 2.....	"	1,970	Suspicious.
" 3.....	"	350	
G. Hull's well, 208 William St	"	21,960	Very bad.
— Duncan's well, 133 Park Ave....	"	590	
— Bier's well, 216 Park Ave.....	"	2,340	Suspicious.
— Yeates' tap (dead end), 227 Chatham St.	"	170	
Dr. Digby's well, Market St.....	"	930	

In the matter of dead ends I would recommend that the goose necks used for filling the watering carts be placed on them where possible, and where this cannot be done some means such as a hydrant be adopted to draw off the water from them at least twice a week.

Milk Supply.—Regarding this article of food, which enters to so great an extent in its raw state into the diet of a community, a close watch has been kept over the dairies by periodic inspections and the supply itself by frequent tests. But since milk often forms a good nidus for the development of bacteria, and forms thereby a possible source of infection, too much care cannot be urged on the milkmen, and where bottles are used they should be subjected to sterilization.

Again, as regards the possibility of tuberculosis in cattle being transmitted through milk having been established, the action of this board is to be commended on the stand it has taken in the enforcement upon all milkmen who supply this city the necessity of having their herds and those from which they obtain supplies subjected to the tuberculin test as provided free by the Dominion Government through their veterinary inspectors, and granting permits to only those who can produce from such veterinary inspectors a clean bill of health of his herds, etc.

Sanitary Inspector's Report.—During the year 150 complaints have been filed at this office, all of which have been investigated and satisfactorily disposed of. Besides the above and inspections of premises where there occurred contagious diseases, there have been 200 house to house inspections. There has also been a thorough inspection of all hotels in the city.

All the thirty-two dairies supplying the city have undergone inspection—once in November and December, 1897, and parts of them again in March and July, 1898. The conditions show a marked improvement in the matter of light, ventilation, drainage and general cleanliness of both cattle and byres.

There have been made from time to time milk tests, the results in a number of cases not being as satisfactory as they should, and the milkmen have been notified to get up to the proper standard or forfeit their permits.

The dairymen have been notified *re* the tuberculin test of herds to be made by Government Veterinary Inspectors, as passed by the board at its meeting in September.

There have been fifty sewer connections made during the year.

There has been a number of water samples collected from time to time during the year to be sent to the Provincial Bacteriologist for examination.

There has been a great many books, etc., from the free library, schools, etc., sterilized from homes where there had been contagious diseases.

In the most of cases where contagious diseases existed, especially diphtheria and scarlet fever, placards have been put up, disinfectants supplied and disinfection done under the supervision and direction of the sanitary inspector.

Fifty privy pits have been cleaned, abolished and replaced by dry earth closets or sewer connection.

There have been issued twenty-five general nuisance notices not included in the above.

(Signed)

J. T. WALLACE,

Sanitary Inspector.

In conclusion I have to regret that other matters have prevented the council from as yet taking any action on the recommendation of this board for a general garbage system, but hope in the near future it, along with the much needed isolation hospital, will be added to the city.

F. G. E. PEARSON,

Medical Health Officer.

N.B.—Since writing this report two new cases of diphtheria have developed at the Institution for the Blind. The rest of the inmates are being subjected to inoculation with antitoxin.

F. G. E. P.

CHATHAM.

REPORT OF MEDICAL HEALTH OFFICER.

November 15th, 1899.

To the Chairman and Members of the Chatham Local Board of Health :

GENTLEMEN,—I herewith submit to you my annual report extending from December 1st, 1897, to December 1st, 1898 :

Contagious Diseases.—The following cases of contagious diseases were reported :

	Cases.	Deaths.
Scarlatina	9	none
Diphtheria	29	1
Typhoid Fever	61	1
Tuberculosis.....	not reported	9

Smallpox.—On September 18th a telegram from the Medical Health Officer of Detroit was received, stating that a veiled woman suspected of having or being exposed to smallpox had escaped their quarantine and started for Chatham.

The woman was located in a Queen street home in a family of four grown-up people and one child. It was found that she was in the seventh or eighth week of the disease, and many of the points of eruption were still covered with scabs, hers being probably the first case carried from Put-in-Bay to Detroit and not discovered by the authorities until the day of her escape here after having infected a number of persons.

The house and individuals in it were promptly quarantined ; the inmates were vaccinated, as well as all others whom we thought might have been exposed. The quarantine was continued for sixteen days. During this time the house was constantly watched night and day by a relay of watchmen and all supplies brought to them. The total extra expense to the municipality in this case was \$95.78.

Scarlet Fever.—There were four distinct outbreaks of this disease in a mild form. Prompt and careful isolation prevented its spread. Total number of cases, nine, with no deaths.

Diphtheria.—There were seven distinct outbreaks of this disease with a total number of cases of twenty-nine with one death. Twenty-three were treated at contagious disease hospitals; six at home. The almost universal use of diphtheria anti-toxin has robbed this disease of much of its terrors. The profession and public now realize that when it is used early and in sufficient quantity the danger from the disease is very much reduced. The excellent work accomplished in the contagious wards of St. Joseph's and General Hospitals has not only done much to prevent the spread and accomplish the cure of scarlet fever and diphtheria in this municipality but in all those contiguous to it. The total number treated in these wards were forty-two, with three deaths.

Typhoid Fever.—Sixty-one cases of typhoid fever were reported, with one death. Fifty-one of these habitually used well water only. Eight were attributed to sewer or other ground contamination. In two others the cause was uncertain.

It is gratifying to notice that for the last few years the disease is decreasing, and there is no fact more plainly brought out in our annual reports than that the improvement is owing to the increased number of persons using the city water supply. The number of householders using city water at present is 977. Our city water works is no longer an experiment but a permanent institution. The water is of excellent quality, abundant in quantity, and reasonable in price. There is no longer any excuse for citizens living on streets where water mains are laid, to use well water, which at best is only soakage water of very uncertain quality and questionable origin.

Consumption.—As this disease is not yet reported as a contagious disease it is impossible to make a report as to the number of cases, but a total of nine deaths has been reported for the year.

Total Mortality.—Total number of deaths from all causes, 159. This includes ten stillbirths.

Death Rate.—16 to 1,000 or 1.6 per cent.

Sewers.—A number of new sewers have been constructed or are now under way. Five thousand eight hundred feet were ordered by this board as sanitary improvements under the by-law, and 6,799 feet were regularly petitioned for, making a total of 12,599 feet, ranging in size from ten to twenty inches, an average of about fifteen inches.

All of which is respectfully submitted.

WM. R. HALL,

Medical Health Officer.

HAMILTON.

REPORT OF MEDICAL HEALTH OFFICER.

November 15th, 1898.

To the Chairman and Members of the Local Board of Health :

GENTLEMEN,—I beg to report on the sanitary condition of the city for the year ending 31st October, 1896, as follows :

Death Roll.—During the year 734 deaths were recorded, of this number twenty-five were non-residents, which are not included in our mortality. Six citizens died while absent from the city and are included. Our citizen mortality was 709. Taking the population at 51,011 (as given by our assessors) the death rate per 1,000 was 13.87. The previous year gave a death-rate of 11.85, which was exceptionally low.

Deaths from accident number nineteen, of which four were non-residents. There were five cases of suicide, same number as last year. Seven deaths occurred at the House of Refuge, two at Aged Woman's Home (one due to accident), eight died at Home of the Friendless and two at the Jail (one a non-resident hailing from Beverly).

Deaths of children under one year old, 158. One year and under five number 57. Total under five years, 215.

Rate of ward mortality per 1,000 of the population shows—ward one, 11.73; ward two, 15.08; ward three, 11.93; ward four, 14.45; ward five, 16.67; ward six, 13.45; ward seven, 13.99. Wards two and five showing a marked preponderance over the other wards. The pop-

ulation of ward two was 5,832, with eighty-eight deaths, and ward five, 6,416, with 107 deaths. All cases dying in our hospitals are recorded in the wards where they resided previous to admittance.

Contagious Diseases.—The number of contagious diseases have not been very alarming. There were 162 cases of diphtheria reported, which shows a rate of 3.17 per 1,000 of the population were reported, with twenty deaths. Last year only 62 cases were reported with fourteen deaths, whereas this year we have 100 cases more with only twenty deaths. Some physicians might impute this to the use of anti-toxin, but I attribute it to the mildness of the cases, some of which were of doubtful diagnosis. Scarlet fever cases reported were 214, giving a rate of 4.10 per 1,000, with ten deaths. Thirty-seven cases of typhoid fever, or .72 per 1,000 of the population were reported, with six deaths.

The other contagious diseases reported were thirty-five cases of whooping cough, with two deaths (thirty of these cases occurred at the Boy's Home), twenty-three cases of measles, eighty-six cases of chicken pox and eight cases of mumps.

Totals of all contagious diseases number 565, showing a rate of 11.07 per 1,000 of the population.

Garbage.—Dumping grounds no doubt contain the elements of disease and in my opinion it would be advisable to have them covered over as quickly as possible. Indeed the proper thing to do would be to make ground as the work proceeds, instead of scattering the refuse, etc., over a large area.

All flesh and vegetable matter and clothing should be destroyed by cremation; they contribute only in a small degree towards making ground.

An incinerator is a necessity.

Milk Inspection.—I would earnestly direct the attention of your Board to the necessity of having the milk by-law amended. I refer particularly to the latter part of rule 11, referring to giving duplicate samples, which is quite unnecessary, as the Dominion Act sufficiently guards the interests of the milk dealers. The clause is now used as a pretext for not supplying samples in accordance to rule X. Other amendments might also be made in the interests of our citizens.

A few days ago the Dominion inspector was in this city; in company with our milk inspector he visited several cow byres in the county. He gave due praise to some of them while others were stated to be simply abominable. This state of affairs should be rectified by proper inspection. It would seem that inspections made by county officials cannot be depended on.

The inspectors annual statement is appended, as also the usual forms.

Respectfully submitted,

(Sgd.) I. RYALL,
Medical Health Officer.

Hamilton, Ont.,
15th Nov., 1898.

CITY HALL, HAMILTON, November 19th, 1898.

TO DR. RYALL,
Medical Health Officer.

DEAR SIR,—Below please find summary of work by milk inspector from November 1st, 1897, to 31st October, 1898, inclusive:

Number of milk licenses isened, good to April 30th, 1898	206
Samples collected and tested.....	414
Dairies inspected.....	193
Cow byres "	168
Shops "	160
Cows reported in a dirty condition and notified to clean	5
Yards dirty and notified to clean.....	3
Cow byres dirty and notified to clean	1

Respectfully submitted,

(Signed) L. O. MACDONALD,
Inspector.

CITY HALL, HAMILTON, November 7th, 1896.

TO DR. RYALL,

Medical Health Officer.

SIR,—Below please find summary of work done by your three inspectors for the year commencing November 1st, 1897, and ending October 31st, 1898, all of which is duly recorded.

Number of inspections made	7,758
“ privy vaults cleaned out by contractors	1,573
“ “ permits given for new ones	31
“ “ abolished	71
“ cesspools cleaned by contractors	24
“ “ permits given for new ones	8
“ dry earth closets notified to be cleaned	50
“ sewer connections notified to be made	17
“ “ found defective and repaired	123
“ foul drains abolished	35
“ stagnant water abolished	25
“ dirty premises cleaned	25
“ other nuisances abated	753
“ old wells filled in	2
“ houses placarded for infectious diseases	260
“ “ fumigated	269
“ loads of refuse delivered at the dump by scavengers	7,504
“ “ from hospital burnt at crematory	54
“ parcels, bedding, etc., from infected houses burnt at crematory	13
“ dead animals collected and buried by D. McBride—dogs, 194; cats, 82; fowls, 33	309

KINGSTON.

REPORT OF THE MEDICAL HEALTH OFFICER.

December 31st, 1898.

To the Chairman and Members of the Local Board of Health:

GENTLEMEN,—I beg to submit the annual report of the sanitary condition of the city, for the year 1898.

Report of Contagious and Infectious Diseases reported.

	Typhoid fever.	Diphtheria.	Scarlet fever.	Whooping cough.	Mem. croup.
January	1	3	1		
February		7			1
March					
April	1	1			
May		4			
June		3	1		
July	1	1			
August	1	1			
September	3				
October		2			
November	3	9			1
December		8			
Total	10	39	2		2

Sanitary Inspections.—The following is a summary of the sanitary work performed during the year:—

Number of permits issued to clean privy vaults	564
Number of cubic feet night soil removed from	21,000
Number of privy vaults filled up with fresh earth	17
Number of privy vaults shallowed to 2½ feet deep	19
Number of privy vaults inspected during the year	2,749
Number of privy vaults reported clean	2,404
Number of privy vaults reported dirty	345
Number of yards and premises inspected during the year	3,881
Number of yards and premises reported clean	3,684
Number of yards and premises reported dirty	197
Number of cellars inspected during the year	2,978
Number of cellars reported clean	2,893
Number of cellars reported dirty	14
Number of cellars reported damp	71
Number of water closets reported in use	832
Number of dry-earth closets inspected	452
Number of dead animals removed from streets, etc	107

Ice.—The ice supply is regulated by provisions laid down by the Local Board of Health. That for domestic purposes is required to be cut in deep water 1,200 from shore, where it is free from sewerage or any other impurity likely to contaminate. For cooling purposes only ice may be obtained in any other section, on permission direct from the Board itself.

All places of storage used, or intended to be used, for domestic or cooling purposes, within the municipality, are subject to inspection by the Medical Health Officer or Sanitary Inspector, and must be clean, wholesome and properly drained and ventilated.

Milk Supply.—The milk supply is at present derived from sixty-three dairies, containing 665 milch cows. Every one of these dairies has been inspected during the year, with regard to the health, food and water supply of the cattle, cleanliness of the byres, drainage, ventilation, light, storage of milk, utensils, etc. The report shows an improvement in the herds, their condition and cleanliness. Samples of milk from the dairies are tested periodically.

Night Soil.—Removal of night soil is done by four scavengers, who are required to have appliances suitable for the carrying on of the work. No pits are allowed to be more than 2½ feet deep (according to by-law), and under no circumstances can pits be partially emptied; they must be thoroughly cleaned, lined and disinfected. The work is required to be done in the day time, except in special cases when permission is granted by special order.

The removal of garbage has become a regular business with persons living outside of the city; so that very little is left for the city scavenger to look after.

Sewerage.—There was constructed during the year $\frac{3}{4}$ of a mile of trunk sewers. This additional drainage will improve the sanitary condition of the city.

Flushing of Sewers.—Complaints of foul smells from the corner gratings have been frequent. In most cases it has been found that decomposing organic matter exists in the sewers, and that flushing is necessary for its removal. The engineer's department is at once notified of the fact, and flushing is at once done. In certain parts of the city the evil is more common and it would be well if a general flushing was done systematically, especially where there is little, or sluggish, flow through the sewers.

It is gratifying to state that the police constables, told off to assist the health department, during the year, in carrying out the work, did good service, and that their aid is duly appreciated.

In conclusion let me say that the location of our city is one naturally highly favorable, from a sanitary point of view. The deaths from contagious diseases this year are as follows:—Typhoid Fever, 3; Diphtheria, 1; Mem. Croup, 1; Whooping Cough, 2. With a good water supply (which we have), and our drainage system completed Kingston will be a healthy city.

I have the honor to be,

Gentlemen,

Your obedient servant,

SAMUEL H. FEE,
Medical Health Officer.

LONDON.

REPORT OF MEDICAL HEALTH OFFICER, ALSO REPORT OF COMMITTEE ON CONSUMPTION.

November 15, 1898.

To the Chairman and Board of Health:

GENTLEMEN,—I have the honor to lay before you my annual report upon the sanitary condition of the city, death rate and other matters relating to the public health for the year ending November 15th, 1898.

The number of deaths during the year was 472, twenty-four of these being due to the lamentable accident at the city hall in January. This does not include twenty-one still-born, which, never having had a separate existence, cannot be counted in mortuary statistics.

Two hundred and ninety-five cases of infectious diseases occurred in the year, as follows:—

Scarlet fever.....	114
Diphtheria.....	108
Typhoid fever.....	46
Consumption.....	26

The last disease is not reported to the health office.

One hundred and ninety-seven cases of infectious diseases were sent to the General Hospital, viz:—

Typhoid fever.....	29 and 1 death.
Scarlet fever.....	55 and 5 deaths.
Diphtheria.....	87 and 3 deaths.
Consumption.....	26 and 2 deaths,

St. Joseph's Hospital received seventeen cases of typhoid fever, with two deaths.

There were ninety-nine deaths from consumption, and fifty-four from all the other infectious diseases combined.

Leaving out consumption it will be seen that of the remaining 188 cases treated in the General and St. Joseph's Hospitals there were only eleven deaths, or a mortality of not quite six per cent.

As patients outside the hospitals are attended by the same physicians as those in the hospitals, the great difference in the death rate in favor of the hospitals can only be accounted for by better sanitary surroundings and better facilities for combating disease, which are not always within reach of the sick in their own dwellings. There is also the fact that several cases sometimes occur in succession in the same dwelling, the first one only being reported.

Of the 472 deaths in the city, consumption is given as the cause of ninety-nine, or more than one-fifth of the number.

At the convention of the Medical Health Officers held in Ottawa in September last, it was shown that there were 3,000 more deaths in the Dominion last year from consumption than from all the other infectious diseases put together, and that in Ontario one person in every 1,000 died annually from consumption. The province last year lost 2,500 wage-earners, and a direct loss of \$2,500,000, and an indirect loss impossible to estimate.

Consumption is contagious, and, therefore, much can be done in the way of prevention.

In this connection the recommendations of the committee appointed by your Board are of such importance to the public that a printed copy should, if possible, be placed in every family, and I would suggest, as the best means of accomplishing this, that these recommendations and instructions to the public be printed on the backs of the assessment commissioners' slips left at each dwelling, and would then unfailingly reach every householder in the city.

There are three clauses in the recommendations of your committee which should be incorporated in the city by-laws relating to public health, or in the Ontario Public Health Act. They are as follows:—

1st. Physicians should report all cases of consumption to the Medical Health Officer for purposes of record, but the placarding of houses where such patients live is not required.

2nd. All deaths from consumption and chronic bronchitis should be promptly reported by the physicians to the Medical Health Officer, so that he may order and superintend such means of disinfection as he may deem necessary, and the city clerk should refuse to issue burial certificates in cases of consumption until the death certificate has been endorsed by the Medical Health Officer.

3rd. Managers of free libraries and other public and Sunday school libraries should not issue books to consumptive patients or their families, and their officials are requested to have printed on their library cards a notice to this effect, "No books will be issued to persons residing in any house where there is a case of consumption, diphtheria, scarlet fever, typhoid fever or other infectious disease."

Cancer caused the death of thirty-five persons. The number of people dying from this disease is, in proportion to the population, increasing every year.

The proposed by-law respecting the sanitary plumbing of buildings is still in abeyance. An excellent plumbing by-law was formulated by the Board of Health and master plumbers of the city. A by-law regulating house plumbing is very much needed in the interest of public health, and it is to be hoped that next year's city council will see their way to pass this by-law.

During the year West London, with a population of 1,885, was annexed to the city, making the population of London now 38,575. The increase in the population of the city during the year, exclusive of London West, was 466. This is a very satisfactory increase and shows the steady growth of the city.

A report upon the condition of herds, dairies and the quality of milk supplied the city during the last six months will be laid before you this month.

The sanitary condition of the city has been very good, and it gives me great pleasure to again report an exceedingly low death rate—12.3 in every 1,000 of the population. This is the same as last year, and when the new system of trunk sewers shall have been completed there is every prospect of this death rate being reduced still lower.

Your obedient servant,

T. V. HUTCHINSON, M.D.,

Medical Health Officer.

Cramming in the Schools.—Prof. Bowman moved that the Board approve of the action of those medical men who agitated the question of the over-taxation of pupils in the city schools by giving them more homework than was consistent with their health. Mr. Bowman said the evil had become so great it was necessary that something should be done.

The motion was approved, and a suggestion by Mr. Pritchard that Prof. Bowman, Dr. Campbell and the mover be a committee to confer with the School Board on the matter, will be carried into effect.

The Board approved of the action of city medical men in speaking against the cramming methods prevailing in the public schools.

Alderman Taylor presided, and also present were Prof. Bowman, Messrs. Christie and Pritchard, Dr. Campbell and the Board officials.

The report of the committee on consumption was as follows :—

Consumption is the most prevalent and the most fatal of diseases in Canada. Last year in the Dominion there were 3,000 more deaths from consumption than from all other infectious diseases. In Ontario one person in every 1,000 dies annually from consumption. Last year the province lost 2,500 wage-earners from this disease—which means a direct loss of \$2,500,000, and an indirect loss of an almost incalculable sum besides. In London this year out of 472 deaths ninety-nine were from consumption, and fifty-four from diphtheria, scarlet fever and typhoid, so that about twice as many died in this city from consumption as from all other infectious diseases. Two deaths in every nine were from consumption.

Consumption is contagious, therefore, many deaths from this disease might be prevented. It is also curable in many cases when taken in time.

The hygienic remedies for consumption are pure air and pure food. To secure proper treatment for the majority of people, sanatoria in rural districts are recommended—institutions to which consumptives can be sent as soon as the disease is detected, where they can receive proper care, while at the same time their families and homes can be protected from contagion. This work will have to be done by municipalities, with such aid as may be received from philanthropists. As London has taken on itself a heavy burden this year in the matter of hospital construction, it cannot be expected for some time to do anything in the way of a consumptives' sanatorium. But there is a great opportunity here for private effort by the citizens in this respect, following the example of Toronto, which has lately appointed a local committee to proceed with the establishment of a sanatorium. The only one at present in operation in Ontario is situated in Gravenhurst.

Meanwhile, there are duties and responsibilities resting upon citizens and municipalities alike, the careful observance of which cannot but result in great benefit on the community and the saving of many lives.

As the poisonous germs of consumption are disseminated largely through the dried sputa, or matter expectorated by diseased persons, special care should be taken with this substance to prevent the spread of contagion.

There should be no spitting in public buildings, conveyances or on the streets. Persons with cough should always use a handkerchief or vessel provided for the purpose. The former should be burned and the latter purified frequently by some strong disinfectant. In street cars and other public conveyances, and in public buildings placards forbidding spitting should be posted, and a sufficient number of spittoons provided. These spittoons should be cleaned daily with boiling water and a strong disinfectant.

In order further to avoid danger from infected dust the rooms occupied by consumptives should have no carpets or unnecessary furniture, ornaments, curtains, etc. The floors should be wiped with a damp cloth, and no broom used. The room should be frequently disinfected, invariably after the death or removal of a patient.

As consumption may be conveyed through meat and milk, special care should be taken by the Board of Health and its officials that no diseased articles of food are sold. It is further advised that milk should be boiled before it is used.

Physicians should impress upon all consumptive patients and their friends the communicable nature of the disease. They should report all cases to the Medical Health Officer for purposes of record, but the placarding of houses where such patients live is not required.

The managers of the free library and all other public and Sunday school libraries should issue no books to consumptive patients or their families, and these officials are requested to have printed on their library cards an announcement to the effect that "no books will be issued to persons residing in any house where there is a case of consumption, diphtheria, scarlet fever, typhoid fever or other infectious disease."

The Medical Health Officer shall report monthly to this Board the deaths from consumption and other infectious diseases.

The city council is requested to amend its by-laws wherever necessary to assist in carrying these recommendations into effect.

The report was received and adopted.

OTTAWA.

REPORT OF THE MEDICAL HEALTH OFFICER.

Dec. 19th, 1898.

To the Chairman and Members of the Local Board of Health :

GENTLEMEN,—I beg to lay before you the annual report of the Health Department for the year ending 31st October, 1898.

In so doing I have to crave your indulgence and apologize for its brevity and incompleteness owing to causes too well known to every member of your board to need repetition here. I am pleased, however, to record the fact that during the period comprised in this report the public health has been generally good, as evidenced by a smaller death rate than that of the previous year, notwithstanding our large increase of population.

Mortality.—The total mortality for the year just ended, exclusive of still-births, was 1,122, that of the previous year, 1,128.

This, with our estimated population of 56,000, gives us a death rate of 20.3 per thousand, a very fair showing, I submit. 556 out of the total mortality were of children of five years of age and under, including for the period the death roll of the foundling institution, the House of Bethlehem.

Contagious Diseases.—With the exception of measles, an epidemic of which prevailed during the spring months, and cerebro spinal meningitis, cases of which were apparently more common than usual, we have had during the past twelve months less zymotic diseases than in the past three or four years. It is quite evident however, as shown in Table I here appended, that among constitutional diseases, phthisis or consumption, is still by far the largest factor in the make up of our death roll as a cause of death, and every community throughout the civilized world is hopeful that in the near future some effective practical means will be devised to stay the ravages of this fell destroyer.

Table II here attached shows the number of cases of infectious diseases admitted into the isolation hospitals, and the very satisfactory results obtained by the treatment applied or received here.

Tables III and IV here appended show respectively the number of infectious diseases reported in the health office, and the records of the House of Bethlehem for the past year. I regret to say, however, in connection with the former table, that excepting as regards diphtheria and scarlet fever, the figures there recorded are not strictly reliable, owing to the fact that physicians still continue remiss in reporting such cases as typhoid fever, measles, mumps and whooping cough, that occur in their practice.

Ice Inspection.—The ice dealers of this city have willingly complied with the regulations of your board in taking their supplies either from the Ottawa river or from the Gatineau river.

Milk Inspection.—In the early part of the year sixty-four samples of milk taken from the different milk vendors of this city were tested by me with the result that fifty-six samples were found satisfactory and classed as good milk and eight samples as poor milk, and below average as regards butter-fat. In order to protect the consumer in this very important article of food, it is to be hoped that the by-law enacting the production of a certificate of the application of the tuberculine test to dairy farm cattle before the obtaining of a license, passed by the corporation last year, will be amended by the council so as to facilitate its effective enforcement without unnecessary onerous conditions to the milk vendors.

Owing to the dismissal of the sanitary inspector by the council about the last of the summer, an action which, by the way, I cannot but look on as as not unjustified, I am unable to give any details of the work which more particularly pertained to that officer.

In conclusion it is my unpleasant duty to protest against the unfair treatment which your board has been subjected to by the council of the year just ending, as calculated to impair its usefulness to a very large extent, and to retard the initiation of such sanitary improvements the want of which had been felt for many years.

Respectfully submitted,

A. ROBILLARD, M.D.

Discharged	84	3	16	4	8	81	3	35	2	10
Deaths	9	7	2
24 of the above recorded cases were from outside the city.					11 of the above recorded cases were from outside the city.					

Though the mortality here recorded is not very large, still it is larger than it would be under ordinary circumstances, owing to two facts : 1. The very large percentage of croupal or laryngeal cases treated in the hospital during the past year, over one-quarter of the number of cases admitted being such. 2. The fact that quite a few of these cases came to the hospital in a moribund condition, and died a few hours after their admission.

ST. CATHARINES.

REPORT OF THE MEDICAL HEALTH OFFICER.

November 15th. 1898.

To the Mayor and Council of the Corporation of the City of St. Catharines:

GENTLEMEN,—In accordance with the requirements of the Public Health Act, I herewith submit my annual report of the sanitary condition of the city for the year ending the 15th day of November, 1898.

Contagious Diseases.—An outbreak of a mild type of scarlatina and German measles in October, occurring principally among pupils attending one of the schools situated in the Ward of St. Andrew, rendered it expedient in the opinion of the Board of Health to close the public and separate schools in the ward, as well as the Sunday schools, in order to prevent the danger of these affections becoming epidemic.

The trustees of the public schools very properly availed themselves of this opportunity to have the class rooms thoroughly cleansed, and disinfected, and to render more perfect the ventilation and sanitary surroundings. I am of the opinion that, owing to the existence of a substratum of quicksand beneath the foundation of the school premises at the junction of Church and William streets, a drain should be constructed to carry the subsoil water into the Ontario Street sewer, in addition to what has already been accomplished in the way of sanitary improvement.

Sewerage.—I desire to congratulate the Mayor and Council and the citizens generally on the progressive extension of the system of drains and sewers, and of the installation of the "Miller Automatic Flush Tank," without which no thorough and systematic cleansing and ventilation of the sewers can be accomplished; as the occasional flushing with hose, although useful at the time, is not repeated often enough to prove efficient in removing the decomposing deposits that accumulate in the interim. It is necessary that the sewers should be flushed every day in order to remove effectually these deposits, and to prevent the sewers becoming elongated cesspools which generate offensive and noxious gases.

It is encouraging from a sanitary standpoint that nearly all the newly erected residential buildings have been connected with sewers wherever it is possible to do so; and it would be of great advantage to the health and comfort of those concerned if cesspools could be entirely abolished in the case of houses situated on streets furnished with sewers.

Nearly every year complaint is made of the peculiar milky appearance, and disagreeable odor and taste of the city water. As this condition of things led some of our citizens to fear that the water was unwholesome, I sent samples of it on two occasions to Dr. McKenzie, the Bacteriologist of the Provincial Board of Health, for analysis; and am pleased to be able to state that his report on both occasions was satisfactory. He assured me that the city water was "good public water," and that it was devoid of any pathogenic germs.

The attention of the Board of Health having been called to the proposed intention of the authorities of the Township of Humberstone, in the County of Welland, to drain the swamp and lying east of the Welland canal into that channel, an act which would tend to pollute the waters of the canal, and injuriously affect the purity of the water supply of this city, I communicated the facts to Dr. Bryce, the Secretary of the Provincial Board of Health, and that gentleman promised to take prompt action to protect us. He has faithfully, and I hope successfully, given effect to this assurance; and I consider that he is entitled to the cordial thanks, not only of the citizens of St. Catharines, but also of those of Welland and Merriton, whose sanitary interests were threatened by the proposed tapping of the canal for drainage purposes.

The Sanitary Inspector and Secretary of the Board have faithfully discharged their respective duties. Their reports are herewith submitted.

On consulting the accompanying report of the Secretary it will be observed that the total number of deaths from all causes occurring in the city from the 15th November, 1897, to the 15th November, 1898, was 165. Deducting from this number the deaths from old age, premature births, and accidents, twenty-five in all, I find the rate of mortality, calculated upon a basis of population of 10,274, is 13.60 per 1,000 of inhabitants.

Respectfully submitted,

E. GOODMAN, M.D.,

Chairman.

REPORT OF SANITARY INSPECTOR.

To the Chairman and Local Board of Health of the City of St. Catharines :

GENTLEMEN,—I have the honor herewith to submit my annual report (as Sanitary Inspector of your honorable Board) for the year ending November 15th, 1898, and say :—

That I have placarded 33 houses during the year, in compliance with the medical returns of contagious diseases.

I have frequently visited the cow-byres, slaughter-houses, livery and hotel stables, canning and other factories within the city when necessary, and have found them generally in a cleanly and sanitary condition.

The city sewers have been frequently flushed during the year, and have been disinfected when necessary.

The streets, lanes and yards have received my strict attention, and I am pleased to say that they have been kept clean generally.

The city scavengers have removed about 1,000 barrels of night soil during the year, and the work has been well and thoroughly done.

I have tested the milk sold by the vendors thereof, and the average registration has been 90 and 92, and no complaints of the quality has been made.

I have made 1,060 house to house inspections during the year, and am pleased to say that I was kindly received by all persons in connection therewith, who showed a willingness to comply with all orders and instructions in regard to sanitation.

I have made weekly visits to our City Isolated Hospital during the year, and have pleasure in saying that the said institution is in good order and condition, and ready for use should necessity require it at any time.

Respectfully submitted,

A. BOULDEN,

Sanitary Inspector

ST. CATHARINES, 17th November, 1898.

REPORT OF SECRETARY.

To the Chairman and Local Board of Health of the City of St. Catharines :

GENTLEMEN,—Herewith I have the honor to submit the annual statement of the number of deaths in the City of St. Catharines from November 15th, 1897, to November 15th, 1898, and the causes thereof ; also statement of the number of contagious diseases for the same period as per medical returns :—

ST. CATHARINES, 17th November, 1898.

ST. THOMAS.

REPORT OF THE MEDICAL HEALTH OFFICER.

ST. THOMAS, 1st April, 1899.

To the Chairman and Members of the Local Board of Health:

SIR,—In compliance with the requirements of the Public Health Act I have the honor to submit the annual report for the city of St. Thomas for the year Dec. 1st, 1897, to November 30th, 1898 :

The sanitary condition of the city has been good. Since the construction of sewers in almost every street and the provision of a sufficient supply of pure water typhoid fever and dysentery are of rare occurrence. We have at present upwards of twenty miles of sewers, and during the year another half mile has been added. They all empty into a common trunk sewer. I hope soon to be able to report that every street is properly drained.

The pit system is still in use to some extent, but gradually water closets are taking their place. As we are not using well water there is no contamination of water by pits and out door privies, the only injury being a noxious state of the atmosphere at night. The reason we do not require all householders to adopt the water closet system is that on a few streets there are, as stated, no sewers, and therefore no proper method of carrying out that system.

Following is the number of contagious diseases placarded during the year, and also the total number of deaths from other causes :

	Cases.	Deaths.
Diphtheria.....	36	2
Scarlet fever	22	1
Typhoid fever.....	2	2
Tuberculosis	13
		— 18

I have no means of knowing the number of cases of tuberculosis.

The number of deaths from other causes than contagious diseases was 102, making in all 120 deaths in a population of 11,250, or 10.66 per 1,000

WM. C. VANBUSKIRK,
City Physician.

STRATFORD.

REPORT OF THE MEDICAL HEALTH OFFICER.

STRATFORD, November 1st, 1898.

To the Chairman and Members of the Local Board of Health:—

GENTLEMEN,—In submitting my report upon the sanitary condition of the city for the past year, I have pleasure in stating that our total mortality during that time was not materially increased from that of previous years.

Deaths.—The total number of deaths during the year was 89.

	Between 80 and 90.....	11 died.
	“ 70 “ 80.....	8 “
	“ 60 “ 70.....	9 “
	“ 50 “ 60.....	12 “
	“ 40 “ 50.....	7 “
	“ 30 “ 40.....	6 “
	“ 20 “ 30.....	12 “
	“ 15 “ 20.....	4 “
	“ 10 “ 15.....	3 “
	“ 5 “ 10.....	4 “
	“ 1 “ 5.....	5 “
	Under 1 year.....	7 “
	Age not given.....	1 “
	Total.....	89 died.

30 occurred in Romeo Ward.
24 “ “ Shakespeare Ward.
13 “ “ Avon Ward.
13 “ “ Falstaff Ward.
9 “ “ Hamlet Ward.

Cause of death as given.

Consumption.....	14	Apoplexy.....	1
Heart failure.....	8	General debility.....	1
Cancer.....	8	Croup.....	1
Old age.....	9	Bright's disease.....	1
Pneumonia.....	6	Lung trouble.....	1
No cause given.....	6	Insane.....	1
Accident.....	5	Asthma.....	1
Typhoid fever.....	2	Paralysis.....	1
Diphtheria.....	4	Convulsions.....	1
Scarlet fever.....	1	Kidney disease.....	1
Measles.....	1	Endocarditis.....	1
Rheumatism.....	2	Liver complaint.....	1
Diarrhoea.....	2	Congestion of brain.....	1
Appendicitis.....	2	Operation.....	1
Inflammation of bowels.....	2	Growth on head.....	1
Dropsy.....	1		

Of the infectious diseases there were : Typhoid fever, 18, with 2 deaths ; diphtheria, 32, with 4 deaths ; scarlet fever, 17, with 1 death.

Consumption.—Consumption still heads the list as regards the number of deaths. It is gratifying to know, however, that the public, as well as the medical men, are becoming alive to the fact that the disease is communicable from one to another. It is now being classed amongst the infectious diseases. Physicians and scientists, not only in this country but also in European countries as well as in the United States, are doing all in their power towards the devising of ways and means to combat tuberculosis. In the monthly report issued by the Provincial Board of Health for September, the deaths from contagious diseases in the Province, as reported to the Registrar-General by the division registrars, throughout the Province 250 deaths were reported : 11 died from scarlatina, 33 from diphtheria, 44 from typhoid fever and 147 from tuberculosis, or 0.8 per 1,000 per annum, while the next highest, typhoid fever, was 0.2 per 1,000. The co-operation of societies having for their object the promotion of public health, the assistance of the public press, and the influence of legislation, will all be required to successfully carry out the desired end.

During the early part of the year we seemed to have been threatened with an epidemic of that much dreaded disease diphtheria, but strict vigilance on the part of your Inspector, together with the assistance of the medical attendants, in seeing that proper precautions were taken as regards isolation and disinfection, prevented its spread. Since the introduction of anti-toxin in the treatment of this disease a few years ago, a remarkable diminution has taken place in the mortality, only four deaths occurring out of the thirty-two affected.

Sanitary Inspection.—The usual amount of sanitary work was done, a general house to house inspection was made ; the water supply in houses where contagious diseases existed was examined ; the several dairies were visited, and the milk supply from time to time received attention, and on all occasions found satisfactory.

Sewerage.—The Sewer Committee reports satisfactory progress towards sewer extension, and the arriving at a satisfactory method of sewerage disposal. The uncalled for action of a neighboring municipality in menacing private individuals and institutions by dragging them into expensive lawsuits, when its Council was struggling earnestly with this important and hard-to-be-decided problem, merits censure rather than commendation.

J. A. ROBERTSON,

Medical Health Officer.

WINDSOR.

REPORT OF THE MEDICAL HEALTH OFFICER.

Dec. 1st, 1898.

To the *Members of the Board of Health* :

GENTLEMEN,—In presenting this, my annual report, I desire to say, by way of premise, that I have endeavored to avoid duplicating any portion of the reports of the secretary and the sanitary inspector.

I had noticed that on more than one occasion the secretary's report overlapped ground already traversed by the medical health officer and, believing that this tended to weary those who may be interested enough to peruse them, I requested those officers to present full reports upon the work covered in their respective spheres, so that nothing should be overlooked in this mode of reporting.

In dealing in this manner with the business of the year, I feel freer to draw your attention to what has been left undone, rather than to what has been effected ; and I do so at considerable length for the reason that the subjects included in the former were more varied, more subtle in the undermining of the public health and less readily grasped, on the nonce, by the average citizen.

To illustrate this point, I need only mention the fact that milk from tuberculous cows may be entering households that know nothing, by actual experience, of the deadly sewer gas (for want of a connection with our sewer system), nor are in danger from water-borne microbes or bacilli by reason of their using filtered or boiled water only.

In this connection, I would introduce an address prepared for my first meeting, officially, with this board, but which I did not then present because of the manner in which I was greeted on that occasion.

I have recently gone over the ground again, in the added light of observation and the study of the reports of the Provincial Board of Health, the reports of the Medical Health Officers throughout the Province, and the papers read before the meetings of the association of those officers, and I find that that address contains much that calls for your attention in the immediate future. I accordingly submit it as part of this report.

With regard to the inspection of the cow-byres and dairy farms, I can but conclude that, up to the time of the visit of Mr. Kidd, it had been but little short of a farce ; and considering it such, I deemed it my duty to draw your attention thereto, and to ask for your active interference. To that end I had prepared a report for your meeting in October, but my efforts in that direction were thwarted by the waste of time upon a matter that was entirely irrelevant. An appeal to the chairman, though supported by the signatures of the majority of this board for a special meeting met with a flat refusal. I had hoped to effect an arrangement whereby the visit of the Dominion Government officer could be utilized for the benefit of the milk consumers, and that he should be accompanied on his rounds by some members of this board. Having failed, as above stated, I throw the responsibility for the miscarriage upon your chairman, and ask you to lay the report referred to before the council.

On the 29th of August I submitted to the council a report upon the examination of sixty-eight samples of milk collected by the sanitary inspector, from the milk vendors ; and, as it was referred to the finance committee for consideration, I prepared a special report upon the inspections that had been made up to date, in order that the whole question might be considered intelligently and with the view to remedying, as far as possible, the evils that had been permitted to grow up. At the request of that committee I examined twenty-four more samples—collected from some of the vendors previously visited, and eight samples from vendors who had been overlooked on the first rounds. I also collected twenty-four samples—some of them skimmed for my examination from parties who kept cows for private use only. This latter step was taken because the milk vendors claimed that the pasturage was responsible for the condition of the milk they had offered for sale, and proved very serviceable in estimating the situation properly. Upon these last samples I also reported and elaborated my former deductions.

As these several reports traverse the field pretty thoroughly, I have asked the finance committee to recommend to the council that they be referred to your committee on “ food, meat and milk supply.”

In this connection I would draw your attention to the report of Dr. Griffin, M. H. O. for Brantford, in which he states that by vigilance and perseverance, the average of butter fat in the samples examined by him had reached 4.53 per cent. ; while, notwithstanding the repetition of examination by your milk inspectors, the average this year is only 3.45 per cent. in the sixty-eight samples examined.

I wish to put on record the very satisfactory manner in which the board of education met the wishes of the Provincial Board of Health as regards exacting the certificates of successful vaccination from each and every pupil ; and I am more than pleased to know that this exaction is to be continued in the future, for it will, in a few years, secure for thousands of our people a protection against smallpox that will obviate the necessity for proclaiming “ public vaccination.”

About 200 children have been successfully vaccinated in connection with my arrangement with the Sisters of the Hotel Dieu, and the results have been, on the whole, satisfactory and in strong contrast with those that obtained in connection with the vaccinating of the school children in 1894. I estimate that fully one thousand vaccinations have been made among school children on this occasion. This, together with the 1,200 vaccinated in 1894, places our school population on fairly satisfactory footing from this standpoint.

I find that by-law No. 877, “ Public Health,” does not contain a clause providing for the inspection of our ice supply, nor for defining and regulating the source from whence that supply shall be obtained. This is a very serious oversight, and should be at once remedied in order that this season's cutting may be supervised and put beyond a doubt as to its purity.

I learn from conversation with the physicians of this city that the use of antitoxin is becoming general, and now that a reliable article can be obtained on very short notice, no hesitation occurs in administering it.

The statutes provided for the inspection of the school houses and their environment by the M. H. O., when so requested by the Board of Health. I presume that their condition is satisfactory to this board, as I have not been asked to do duty in this respect.

So far as I can learn this Board has had no report from any source as to the condition of our water supply and has not taken any steps to that end. I cannot understand how this very important matter has been overlooked by your committee on "plumbing, sewerage and water supply." In Toronto and elsewhere the M. H. O. is authorized by the council to have the necessary examinations made from time to time. Taking advantage of Mr. Kidd's visit here, and the nature of the instructions from the Dominion Analyst, I asked him to send a sample to Ottawa, and I expect to have a report thereon in my own hands shortly.

The diphtheria regulations, though adopted by order-in-council on Dec. 23rd, 1891, have not, as yet, been put into force in this municipality, and though By-law No. 877, passed was subsequent to their promulgation, does not provide for their being complied with in some very important respects.

I would have brought this matter to your notice before, but I was told in March last, by resolution of this Board to reserve all such matters for my annual report in December. I must insist on a change being made in this respect, or I shall be compelled to report, as provided for in clause No. 2 of these regulations to the Provincial Board, "default on the part of the authorities."

In these regulations the M. H. O. is enjoined to do certain things that I find it impossible to comply therewith on account of the manner in which the business of this Board is conducted under By-law No. 877.

The Provincial Board of Health for instance has provided for the examination, microscopically, of the sputa and portions of false membrane expectorated by any suspected case of diphtheria so as to facilitate an early diagnosis, but, so far as I have learned this golden opportunity has not been utilized by any officer of this Board, nor is it likely to be under existing conditions.

I notice that the Provincial Board of Health at its last meeting debated, at considerable length, the necessity of adopting some system of examining the school-children daily and following up any case of suspected contagious disease in order to prevent the spread of such diseases among the children. The outcome of the debate was the passing of a resolution recommending daily visits by physicians who should trace all suspected cases, if possible, to their origin.

It has frequently been demonstrated beyond a doubt that, to the mingling of the affected children among the unaffected has been largely due the very rapid and extended spread of one or other of the contagious diseases, and, doubtless, in time, some means will be found to cover the field efficiently.

I have notified all the medical practitioners in the city of the resolution passed in '93 or '94 requesting the notification to this Board of cases of typhoid fever, as I found it was not being done.

The experience of the year points to the desirability of the M. H. O. having some sort of supervision over the use of the city ambulance.

I would suggest that forms for reporting to this Board all cases of suspected contagious diseases coming to the knowledge of any public school teacher, be furnished to each Principal for such purpose. In this way cases that are not being attended by any physician will become known to this Board officially.

In conclusion let me draw your attention to the provision in clause 16, By-law No. 877, with regard to the abolishment of the privy vault or pit along the lines of the sewered streets next year, with the view to suggesting that preparations be made to inaugurate the campaign with the beginning of the new year (1900).

All of which is respectfully submitted.

R. CARNEY, M. H. O.

REPORT OF THE SECRETARY.

WINDSOR, December 1st, 1898.

To the Chairman and Members of the Board of Health :

GENTLEMEN,—Pursuant to the provisions of section eleven of the Public Health By-law, I have the honor to submit for your consideration the following annual report upon the "Sanitary Work" done during the year, as well as upon the "Sanitary condition of the Municipality."

Sanitary Work.—The annual cleaning of yards, alleys, etc., and the removal of the rubbish and other accumulations therein during the winter months, was perhaps more thorough this than in any previous year, the work of gathering and carting the same to the dumping ground having been effected not by day work as hitherto, but by means of a contract with Robert Briody, whose undertaking required him to continue at the job from the beginning of March until the 24th May, the price being \$250. The Inspector superintended the work constantly and was well satisfied with the manner in which Mr. Briody observed his obligations.

A more suitable dumping ground than the old one was secured from Mr. Briody at an annual rental of \$40, the location being remote from residences and of easy access. Six hundred and twenty-five closets in outlying parts of the city have been cleaned out at an average cost to the parties of \$1.25 each.

The plumbing by-law has been very generally enforced, and all new work as well as alterations and repairs, have been done under the supervision of and tested by the inspector. Thirteen new and forty old houses have been properly equipped and connected with sewers, and there have been eighty-four cases of drain and plumbing improvement and new plumbing effected—in all 137 cases in which the provisions of the by-law have been complied with.

On the application of owners, who have met the expense of the materials, eight stores and dwellings have been disinfected by the inspector.

The inspector has successfully prosecuted in the Police Court one offender for selling lump-jaw beef, one for selling decayed fruit, and three for maintaining nuisances upon their premises, namely, pig pens in two cases, and old bones and rags in the other. The officer also had destroyed as unfit for food a tierce of pork, a quantity of fish and of chickens.

Milk Inspection.—On August 3rd, no milk inspection having been made up to that date, the board requested the medical health officer to undertake that work at a time to be indicated by the chairman. Accordingly the inspector obtained for the purpose ninety-three samples from resident and non-resident dealers, some of which were taken on the 8th, 16th, 20th and 23rd days of said month. These were examined by the medical health officer, who reported thereon to the council in conformity with the provisions of the milk by-law, instead of to the board, as all previous medical health officers had done, with the result that the board has no knowledge of the nature of his investigation. The by-law, it is respectfully submitted, should be changed so as to require the report to be made to the board.

Contagious Diseases.—Contagious diseases have happily very largely given this city the go-by. Since the 15th December, 1897, there have occurred six cases of diphtheria, two of scarlet fever, two of typhoid and one of smallpox, in all eleven cases. One of the typhoid cases, that of a patient brought here from Michigan for treatment, proved fatal—the only death from any of the diseases mentioned during the year ending the 15th instant. The case of smallpox cost the board a good deal of money, to say nothing of the trouble entailed, and much advertising through foreign newspapers caused by the visitation, which, evidently for the purpose of attracting greater attention, was glibly referred to as an "invasion" of the dreaded disease. It was the case of a tramp, who variously gave his name as George Irving and Edward Maloney. He was locked up in the cells on the 5th February, and the same night was visited by the city physician, prescribed for, and the following day sent to Hotel Dieu, where the nature of his ailment was recognized and his removal from that institution back to the cells ordered by the Sister Superior. The then medical health officer was summoned, and he had the patient taken to the contagious disease hospital the same night. Thomas Davis, an old smallpox nurse, was placed in charge. On the 19th February the secretary of the Provincial Board of Health met the local board by appointment to ascertain the facts in regard to the case, after learning which he approved of the course pursued by the board and instructed the present medical health officer to keep a sharp look out for a person who spent a night in a cell adjoining the one occupied by the patient and who had been released and was at large, and vaccinate him as soon as found—all the other persons in any way brought into contact with him having been protected against contagion. Dr. Bryce also advised that the patient be detained ten days longer in the hospital, which advice was adopted. Nothing has since been heard of the man.

Vaccination.—The question of the general vaccination of the pupils attending the public schools of the city having been raised, a special meeting of the board was held on the 19th of August for the purpose of taking action upon that question. The chairman of the Board of Education was present by invitation. It was decided that in order not to interfere with school work, all the pupils requiring it should be vaccinated forthwith; the board instructed the medical health officer to telegraph for vaccine, appointed a physician to attend to each school house to examine and when found necessary vaccinate the pupils on the roll of such school, fixing the price of the work at 25 cents each pupil; ordered notices to be prepared and delivered at every house in the city, setting out the action and object of the board and affording all needful directions to parents and children; directed the medical health officer to supply the physicians appointed as aforesaid with the necessary vaccine points; authorized the chairman with the medical health officer to fix the precise date upon which the children were to attend at the school houses for examination, etc., and the chairman to supply record books for the use of the physicians, and also requested the medical health officer to prepare a form of certificate to be furnished the pupils for presentation to the teachers on the reassembling of the schools. The vaccine points, however, arrived so late, and some other difficulties arising in the interval, that it was found impossible to carry out the intention of the board; the points were returned unopened, and a warrant issued to the medical health officer for \$12.50 to be remitted for damage done to the points by their double journey from and to Quebec. Later on the Board of Education took the matter up and required all children attending school to produce by a fixed date (November 1st) to their teachers a certificate of successful vaccination. As some parents were confessedly unable to stand the expense of vaccination under the rule of the Board of Education, the Board of Health resolved on October 5th to furnish free vaccination to all poor persons and authorized the medical health officer to vaccinate all who should apply to him with a certificate from the president of the Home of the Friendless of their inability to pay, which certificate was deemed a necessary precaution against imposition. The result of these several steps to ensure protection from contagion for the youth of the municipality, will no doubt be communicated to you by the officer responsible for carrying them out.

The Hospital.—The contagious disease hospital is in as good a condition as a building of that description could well be. Everything necessary for comfortable occupation of patients has been provided and made ready for use. Fuel has been placed under cover, the heating apparatus increased so that two wards can be heated in fifteen minutes without waiting for the slower action of the large furnace, and come what may in the form of smallpox or other similarly dreaded maladies, the board is in a position to treat patients in a prompt, humane, and satisfactory manner.

Perhaps the most important duty the board next year will be called upon to face will be the securing of a new and if possible a more convenient site to which the hospital may be removed, as the existing lease will expire before the end of that year. This fact the over-holding members will do well to keep in mind.

Sanitary Condition of the City.—It is perfectly safe to say that never before in its history has the sanitary condition of the place been as good as at present; and it is as certain that this satisfactory condition of things has been brought about by the persistency of the board in enforcing those by-laws designed to compel obedience to well-established ideas. People generally naturally shrink from expenses the immediate benefit of which they do not perceive. For example, house-owners generally will hesitate to provide effective plumbing and drainage for the premises they rent, and tenants are equally indifferent as to the cleanliness of their holdings, unless some authority backed by the strong arm of the law exercise watchfulness and interpose its power to effect proper conduct on the part of both these classes. So also in respect to isolation of persons afflicted with contagious and infectious diseases—if no restraining influence be exercised from without, people generally will utterly disregard danger and freely place themselves and the public in jeopardy. It sometimes, no doubt, appears like undue severity to compel a rigid observance of preventive measures; but in no other way can the health and security of the community as a whole be subverted; and the marked improvement in Windsor's condition, despite the lamentable state of the decayed wooden pavements on several of the most used streets, is directly and emphatically a tribute to the fidelity to its duties observed by the Board of Health the past few years.

Appended hereto is a table showing the deaths registered since December 15, 1897, to the date of this report and the causes thereof (with the ages of the victims) reported by the physician attending in each case.

I have the honor to be, gentlemen,

Your obedient servant,

STEPHEN LUSTED,

Secretary.

TOWNSHIPS.

Name of municipality.	Names of Medical Health Officer and Secretary of Board.	Is there general sanitary inspection? Is it repeated at intervals every year? or is action taken only when complaint of nuisance is made to Board?	Contagious diseases.
Armour	Wm. Crawford, M.D.; Alex. Mackie.	Typhoid, 2 cases; tuberculosis, 1 case.
Alfred.....	A. A. Gibault, M.D.; Joseph Brisebois.	When complaint is made to the Board.	Typhoid, 8 cases.....
Ashfield	F. M. McLennan, M.D.; Wm. Stothers.	No.....	Scarlatina, 2 cases; typhoid, 2 cases.
Alnwick	T. C. Lapp, M.D.; James Roberts.	Action taken only when complaint is made.	Diphtheria, 9 cases.....
Adelaide	F. J. Bateman, M.D.; H. J. Miller.	General, when the Board considers it necessary.	Scarlatina, about 30 cases
Athol	J. M. Platt, M.D.; Wm Moore.	No.....	Diphtheria, 13 cases.....
Ameliasburg.....	Drs. Thornton, File and Farncomb, M.H.O.'s; James Benson.	Yes; only when complaint is made.	Diphtheria, 2 cases; tuberculosis, 5 cases.
Anderdon	James Parke, M.D.; A. C. Maillaux.	Only when complaint of nuisance is made to Board.	Scarlatina, 2 cases; diphtheria, 3 cases, 1 death; typhoid, 1 case.
Arran	T. F. McNally, M.D.; Jas. M. Monckman.	General sanitary inspection twice a year, and member of Board visits schools once a year.	Typhoid, 1 case; tuberculosis, 2 cases.
Algona, S.....	— Galligan, M.D.; T. McGreath.	No; no; yes	None.....
Arthur	A. J. Reynolds, M.D.; Geo. Cushing.	Yes; and special when complaint is made.	Scarlatina, 2 cases; diphtheria, 3 cases, 1 death; typhoid, 6 cases; tuberculosis, 1 case, 1 death.
Augusta	W. H. Waddell, M.D.; J. W. Place.	No; no; action taken only when complaint is made to Board.	Diphtheria, 8 cases.....
Anson & Hindon.....	C. D. Curry, M.D.; T. H. Rodgers.	Only when complaint is made to Board.	Scarlatina, 5 cases.....
Ancaster	G. D. Farmer, M.D.; Henry Pim.	Annual inspection of Village, of drains and cheese factories.	Scarlatina, 1 death; diphtheria, 6 cases; typhoid, 1 death; tuberculosis, 2 death.

TOWNSHIPS.

Is isolation of contagious diseases systematically carried out? State methods adopted and whether any isolation hospital exists.	Is diphtheria anti-toxine in common use by physicians? Give results of treatment in all cases where possible.	Is disinfection after contagious diseases carried out under the personal supervision of an officer of the Board?	Does the Board make systematic inspection of the public schools? Does it require a certificate of vaccination from new school children each year?
Yes	Yes	Yes	No
Private isolation. No....	Yes	Yes	No; no.....
No	No cases	Sometimes	No..
Isolated at homes; no hospital.	Yes; recently; extremely satisfactory.	Yes	No
Yes; no hospital.....	Yes	Yes	No; No.....
Yes.....	Think it is	Yes	No.....
As far as possible by isolation on premises.	Dr. Thornton, Consecon, has used it successfully in his practice.	Yes	Only when complaint is made; no.
Yes; house placarded	No	By attending physician..	No.....
Isolated and quarantined; no hospital.	No	Yes	Yes; no.....
Yes	Yes; no occasion to use it this year.	Yes	No; no.....
Yes; confined to one apartment of house and premises placarded.	No	The physicians in attendance have the supervision	Yes; no
Yes; when notified by physician.	No	M. H. O. disinfects, but in only one instance has the M. H. O. been notified by attending physicians.	No; no.....
Yes; no isolation hospital.	No diphtheria in 1898; antitoxine used in previous years with success.	Yes	No.....
As far as possible; no isolation hospital.	Used in all cases by M. H. O. with satisfactory results.	Under supervision of M. H. O.	No.....

TOWNSHIPS — *Continued.*

Name of municipality.	Are forms for notification by teachers and M. H. O. of contagious diseases supplied?	Give the source of water supply used on the premises. If from wells, state usual depth of water bearing stratum.	Is there systematic inspection of dairy cows made during the year? Have cases of tuberculosis occurred, and state whether the tuberculin test has been used.
Armour	No	Wells, about 20 feet....	No
Alfred.....	No	Wells, 12 feet.....	No; none
Ashfield .. .	No	Wells	No
Alnwick.....	No	Wells, about 20 feet....	No; no
Adelaide	No	Wells	No dairy
Athol	No	Wells	No; no
Ameliasburg.....	No	Wells	Systematic inspection of cheese and butter factories only.
Anderdon ...	No	Wells, from 30 to 60 feet.	No
Arran	Yes	Wells, from 10 to 40 feet deep.	No dairies in municipality; none
Algona, S.....	Yes	Wells, about 12 feet....	No; no
Arthur	Yes	Wells, from 15 to 25 feet deep.	No; no
Augusta.....	No	Wells, 10 to 15 feet	No; none; lately; no ..
Anson & Hindon	No	Usually from springs....	No
Ancaster	Wells, 14 to 55 feet	Yes; no test.....

TOWNSHIPS.—*Continued.*

How many slaughter houses in municipality? Are they licensed on evidence of being kept in good sanitary condition? How is offal disposed of? Is there systematic inspection of carcasses by any officer of the Board?	Is there systematic removal of garbage, and night soil? If so, on what basis of cost is the removal made? How is cost calculated?	Is there a public sewerage system? If so, what proportion of houses to whole is connected with public sewers?	State No. and kind of noxious trades. (See sec. 63, Public Health Act.) How licensed and regulated?	Have there been any prosecutions during year under Public Health Act? State in detail the nature of the case, and results of same.
2; not licensed; offal fed to hogs.	No	No	None	No.
2; no; buried when required.	No	No	None	No.
2; licensed; offal fed to hogs; no systematic inspection.	No	No	None	No.
1; used but once a week; offal boiled and fed to hogs.	Each family disposes of their own.	No	None	No.
2	No	None	No.
No	No	No	None	No.
.....	No.
None	No	No	None	No.
2; not licensed; offal is boiled and fed to hogs; no systematic inspection of carcasses.	No	2; slaughter houses not licensed, but inspected.	No.
None	No	No	None	No.
One; yes; no inspection of carcasses; meat is sold in the adjoining village.	No; trustees of schools are required to keep water closets in a sanitary condition.	No	None	No.
No	No	No.
One; not licensed; no inspection.	No	No	None	No.
8; no licenses	No	No	No.

TOWNSHIPS.—*Continued.*

Name of municipality.	Names of Medical Health Officer and Secretary of Board.	Is there general sanitary inspection? Is it repeated at intervals every year? or is action taken only when complaint of nuisance is made to Board?	Contagious diseases.
Amabel.	T. Campbell, M.D.; R. Murray.	General sanitary inspection; township divided into divisions, with sanitary inspector for each district.	Diphtheria, 4 cases, 1 death; typhoid, 5 cases, 1 death; tuberculosis, 7 cases, 2 deaths.
Albermarle.	—, Wigle, M.D.; C. E. Wincher.	Action taken when complaint is made.
Assignack.	General inspection at intervals.	None.
Alice & Fraser.	G. E. Josephs, M.D.; J. M. Kennedy.	Only when complaint is made.	Diphtheria, 3 cases, 3 deaths; tuberculosis, 1 case, 1 death.
Amherst Island.	None.	No; no; when called upon.	Tuberculosis, 2 cases ...
Artimesia.	J. G. Hutton, M.D.; W. J. Bellamy.	No; action taken on notice.	None reported.
Adjala.	—, Wright, M.D.; P. J. Haffey.	No; no action, only on complaint.	None.
Alberton.	R. Moore, M.D.; J. D. Stewart.	When complaint is made to Board.	Tuberculosis, 1 case, 1 death.
Burges, N.	No M.H.O.; P. McFarland.	No.	None.
Bexley.	J. Grant, M.D.; Alfred Taylor.	Action is taken when complaint is made to Board.	Diphtheria, 1 case; typhoid, 1 case.
Burford.	R. Harbottle, M.D.; Philip Kelly.	No; only upon complaint.	Scarlatina, 7 cases; typhoid, 2 cases, 2 deaths; tuberculosis, 2 cases, 2 deaths.
Bastard & Burgess, S.	John G. Creegan, M.D.; Walter Beatty.	No; no; yes.	Typhoid, 1 case; tuberculosis, 1 case, 1 death.
Bedford.	—, Parker, M.D.; James McNeil.	Yes; no; action taken when complaints are made.	Tuberculosis, 1 case, 1 death.
Brook.	McDermott & Jardine, M.D.'s.	Scarlatina, 50 cases; diphtheria, 3 cases; tuberculosis, 3 cases.
